Cutting Costs By Saving Fuel

Elesco Superheaters will solve the problem of high fuel cost in your plant.

This saving is possible for you regardless of the product you manufacture, or the type and size steam plant you operate for power.

Fuel is too great an item in your manufacturing costs.

Made in Canada

THE ELESCO SUPERHEATER

applied to meet your operating conditions, will enable you to meet your production schedule on less fuel.

The fuel saving ranges as high as 25 per cent.

It will pay you to outline your fuel problem to our Engineers. They will gladly suggest a practical means by which you can cut the cost of operating your power plant.

Write for Bulletins.

Several Reasons Why "The Cole" Is Superior

By the installation of a COLE Return Trap system in your plant, you not alone get superior machines, but you get the best engineering service.

Do not leave it until too late. Consult us on how to decrease your fuel consumption and increase your circulation.

Our new catalogue is just off the press. Write for your copy.

JENNINGS TURBINE VACUUM AND LOW PRESSURE BOILER FEED PUMP

The distinct advance in principle and design of the Jennings over all other types is the result of many years' experience in the building of turbine vacuum pumps. For return line heating systems, dryer exhaust systems in paper mills, or other vacuum work where large percentages of liquids have to be handled with gas, the Jennings is without equal.

The horsepower required to operate this pump is less than half that consumed by any other vacuum heating pump of the same capacity. The Jennings has two independent turbine units, an air pump and a water pump, combined in one casting, with the impeller of each mounted on the same shaft.

We shall be glad to tell you more about the many distinct features of this pump. Write for full information.

Service—

That one word furnishes the secret of the world-wide popularity of Jenkins Valves.

The genuine Jenkins Valve—with the well-known Diamond Trade Mark cast on body—is made to furnish efficient, lasting service under the most trying conditions of usage. The occasional bit of extra pressure which works havoc with inferior valves will not affect the genuine Jenkins because it is made to withstand strains in excess of that which it will be called upon to endure in actual operation.

And the Jenkins line is complete—a valve for every purpose.

Write for free copy of Catalog No. 8. It describes the entire Jenkins line in detail.

Equipment Bearing an Established Reputation

To the buyer of Power Plant Equipment its reputation should be of first concern. It is of far more consequence than any written guarantee.

The reputation of Belliss and Morcom Engines for long, reliable Service has placed them in many of Canada's largest power plants. They are the invariable choice of Engineers and men who know. When you're in the market do not fail to consider the Belliss & Morcom line.

We would be glad to forward you a list of names of power plants having Belliss & Morcom installations so that you may have an opportunity to investigate their reputation in actual service. Write to-day.

McEWEN HIGH-SPEED AUTOMATIC ENGINES

These dependable engines are built for continuous duty. They are your best insurance against costly repair bills and unexpected shut-downs.

They operate quietly and smoothly with an exceedingly close regulation under fluctuating loads. Sturdiness and their large reserve capacity enable them to respond instantly to heavy peak load demands.

Your careful investigation of their actual service performance record in all parts of the country specially requested. Let us send you our list of McEwen users.

Built in simple and compound units up to 700 H.P. capacity. May we send you descriptive literature?

New Truths and Old Fallacies

Fusibility of Alloys—*Continued*

Theoretically a shaft rests in the bearing upon a thin film of oil or "floats" upon it, and as long as this condition prevails, the true intrinsic value of a babbitt is masked to a considerable extent; and under moderate speeds and loads a babbitt of most ordinary quality will keep going, but the use of such metals involves a greater degree of wastefulness in power, oil, wear, metal, etc., and they are always on the verge of trouble.

It is most important, therefore, to select lubricants of the proper gravity and viscosity to correspond to the size, load and speed of bearings and that will follow quickly the rotation of shaft and thereby always interpose an oil film; the oil grooves must also be cut to facilitate the flow of oil in the direction of rotation. Metallic contact between the shaft and bearings will invariably cause quick heating, and result in seizing and scoring with most metals. It is under just such crucial conditions that Magnolia Metal proves its real intrinsic worth because of its self-lubricating quality.

A white metal alloy of any composition will become too soft to support the load if its temperature reaches around 300° Fahrenheit; and the lower its fusibility, the more susceptible it is to the influence of heat and no degree of hardness will protect it, as we shall undertake to show later.

"White Brass"—a tin-zinc mixture—is affected in the same way, under the same heat conditions, only it loses all cohesion and crumbles into small pieces and also has a tendency to seize. These serious faults have limited its use to bearings not likely to heat or that can be cooled by the application of water. It shows desirable qualities when in a cool state, but is most disappointing in actual service and drosses heavily.

IT SAVES

even where steam is plentiful

Waste is waste wherever you find it. Even where coal is mined, it is poor economy to be prodigal with fuel. By the same sign, even where steam is plentiful, it is a waste of fuel to waste the steam.

If, for instance, each radiator can be heated to 100% efficiency at lower steam pressure, and at the same time not let any steam into the return line, then considerably less fuel is needed. You will not need jet water on a Dunhamized vacuum heating system.

The Dunham Radiator Trap has some very interesting fuel-saving records to its credit—to say nothing of its ability to keep radiators hot all over. May we send you the facts?

Snow-covered for hundreds of feet—*Superheat all the way*

THIS outdoor superheat line is covered with 1½ inch thick Asbesto-Sponge Felted Sectional Insulation, wired on, without canvas, over which are three layers of ½ inch thick Arctic Brand Keystone Hair Insulator, with an outer Johns-Manville weather-proof roofing jacket bound on with independent strands of copper wire.

The remarkable heat-saving quality of Johns-Manville Insulation is clearly apparent when the loss of heat is so slight that snow rests on it, and the steam retains its superheat all the way.

This is but one of the many special insulation problems that Johns-Manville has solved in twenty-five years of experience.

Send to our nearest branch for information about the Johns-Manville Line of Asbestos and Magnesia, Pipe and Boiler Insulations.

Central Illinois Light Co., Peoria, Ill.

LACLEDE

A BUSINESS INSTITUTION

THE STOWE STOKER

EMPLOYING MECHANICAL DRAFT

Its fundamental principle is a conveyor-feed, positive in action from coal-hopper to ash-pit.

Why the Central Illinois Light Co. Purchased the Stowe Stoker

Mr. George Daniels, Mechanical Engineer of the Central Illinois Light Co., Peoria, Ill., who recently purchased a single Stowe Stoker for use in connection with a 1200 H. P. boiler to be operated at 300% of rating, makes the following comment in connection with their selection of mechanical stoker equipment:

"From our experience with various types of automatic stokers, we are convinced that as to the matter of feed, the conveyor feed is the only one to consider where positiveness in action and the automatic translation and discharge of the fuel and its resulting ash are considered. What appeals to us most in the Stowe Stoker is the fact that Laclede-Christy have combined with the Conveyor Feeding a system of Stationary Tuyeres that allows them to graduate the air spaces and the air supply so that each stage of combustion receives a varying amount of air in proportion to its needs."

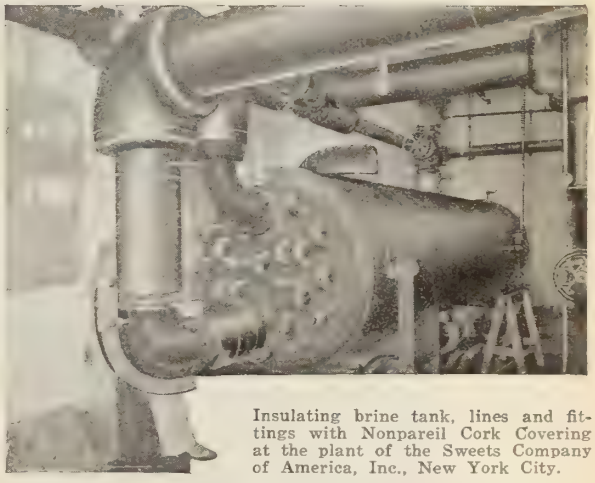
Who "Pockets" the Loss?

BARE brine and ammonia lines are wasters of money—destroyers of profits, yet in many plants the loss from bare and improperly covered cold lines goes on year after year.

Figuring refrigeration at 75 cents a ton, 120 feet of bare 3-inch pipe carrying brine at 15 degrees F. through a room at 90 degrees F., wastes one ton of refrigeration every 24 hours. Owners of uninsulated equipment are, therefore, "pocketing" a considerable loss, 80% of which can be saved by the use of Nonpareil Cork Covering.

The superiority of Nonpareil Cork Covering for reducing waste of refrigeration from bare pipes, tanks, and other cold surfaces is due to the material of which it is made—clean granulated cork. Being cellular in structure, not fibrous, cork is not only a remarkable insulator, but it does not absorb moisture by capillary attraction, become water-soaked and lose its insulating efficiency. Hence, the recognized supremacy of Nonpareil Cork Covering.



Insulating brine tank, lines and fittings with Nonpareil Cork Covering at the plant of the Sweets Company of America, Inc., New York City.

Send for the 64-page book, "Nonpareil Cork Covering for Cold Pipes," and read the evidence by which the superiority of Nonpareil Cork Covering is established.

ARMSTRONG CORK & INSULATION COMPANY, 504 McGILL BUILDING, MONTREAL, QUEBEC, CANADA

Also manufacturers of Nonpareil Corkboard Insulation for cold storage rooms; Nonpareil High Pressure Covering for steam lines; Nonpareil Insulating Brick for b settings; Nonpareil Cork Machinery Isolation for deadening the noise of machines; and Circle "A" Cork Brick for cold storage room floors.

QUALITY YORK SERVICE

York Uniflow Engines for Ice Making and Refrigerating Plants

One of the most important considerations in an Ice Making or Refrigerating Plant is the type of prime mover. An economical ice plant should have a dependable motive power, and one which will maintain a reasonable economy when called upon to operate over a range of from ¼ to 1¼ times the normal load.

It is well known among refrigerating engineers that the best compressor economy is obtained when evaporating pressures are carried as high, and condensing pressures as low, as possible. Even well balanced plants are forced to meet extreme seasonal conditions, with evaporating pressures varying from 20 to 30 pounds and condensing pressures from 85 to 225 pounds. These pressure variations and seasonal requirements of the Trade impose load factors of corresponding variation on the engine operating the compressor.

The Uniflow Steam Engine presents itself as the best solution of this difficulty

In the LARGEST and MOST MODERN PLANT in the WORLD, building Insulated DOORS and allied products exclusively, we are building what we KNOW to be THE BEST INVESTMENT FOR THE USER and the universally recognized WORLD'S STANDARD DOORS. In verification:—

THE HARRIS ABATTOIR CO., Ltd., Canada.

"Our Coolers and Freezers are mostly equipped with your doors. In fact we adopted it as Standard throughout our plant, as we find them substantially made and the insulation perfect. We also find the Hardware stands up better than on any other door we have seen or tried."

LOUISVILLE SOAP CO., Louisville, Ky.

"Coolers at one of our plants are equipped with your doors, which have given us such satisfaction we wish to improve the doors at our old plant. We would not be warranted in throwing out the doors but would like the type hardware you supply."

THE WASHINGTON MARKET, Washington, D.C.

"The doors supplied by you, in use at both plants, have been in every way satisfactory, and we thing the Jamison door is the best on the market."

Read 'em again, men—analyze them! Acquaint yourself fully with our method of construction through latest catalog No. 9—just off the press.

Sectional View Economy Ferrule Type Fuse and Economy "Drop Out" Renewal Link

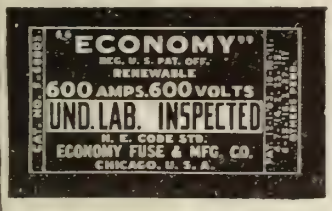
ECONOMY *renewable* FUSES

Sectional View
Economy Knife Blade Fuse

Consider the Fuses in Your Plant

Proper protection of lives, property and machinery in all industrial plants using electrical energy depends upon the accurate functioning of fuses used.

Economy Fuses are absolutely accurately rated. They operate unfailingly when overloads, short-circuits and lightning discharges cause hazards to lives, apparatus and property.



Nothing is destroyed but the inexpensive strip of fusible metal — quickly and easily replaced by a new Economy "Drop Out" Renewal Link.

This feature cuts annual fuse maintenance costs 80% as compared to use of one-time fuses.

Avoid production delays; it requires but a minute to restore a "blown" Economy Renewable Fuse to its original efficiency.

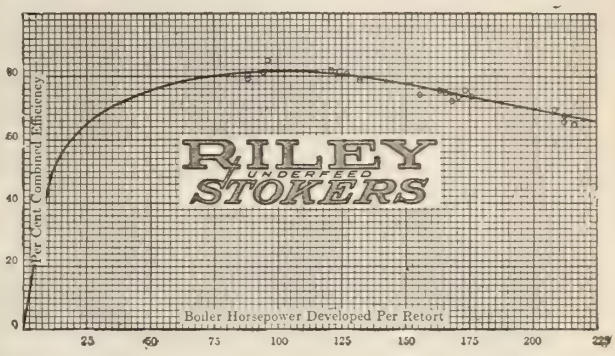
Instruct your electrician to install Economy Renewable Fuses at once.

For sale by all leading electrical jobbers and dealers.

Economy Fuse & Mfg. Co. of Canada, Ltd.
Unity Bldg., Montreal, Canada

Economy Fuses were the first line using an inexpensive bare link for restoring a blown fuse to its original efficiency to be approved in all capacities by the Underwriters' Laboratories.

ARE YOU WASTING COAL?



If your boilers are operating at 65% efficiency, whereas you ought to be getting 75% or 80%, then you should investigate to-day the possibilities of RILEY UNDERFEED STOKERS.

The first year after installing Riley Stokers, the Haverhill Boxboard Company saved ten tons of coal a day, and reduced their operating force by thirty-six men—a total saving of $52,000.00.

Our catalog shows a cut of an evaporation curve. From it you can figure just what you can actually save in dollars and cents by increasing your efficiency.

Catalog HR-10 sent on request.

Goodyear Klingtite Belts saving power in the flour mills of Korea.

World-Wide Acceptance of Goodyear Belts

THERE is a world-wide acceptance of the Goodyear Belting which dominates in Canadian industry.

This direct endorsement of the Goodyear principles of manufacture and application gives us no little pride. It means that the technical men of the world see eye to eye with Canadians in the matter of economical and satisfactory power transmission.

But it means much more to Canadian industry. It means a world-wide fund of data for the Goodyear men who advise with you on belting problems. It means that the cotton spinners of Lancashire, the silk manufacturers of Lyons, the steel plants of Sweden, the shipyards of Seattle, the flour mills of the far East—all will contribute their experience to help solve power problems in Canada.

In order to meet world-wide market conditions it has been necessary to change some of the familiar Goodyear brand names—but the change is in name only.

For example, Goodyear Extra Power Belt is now Goodyear Klingtite Belt, and when the Goodyear belting man specifies Goodyear Klingtite for a certain drive you are getting the old Extra Power in every particular.

Ask any Goodyear branch to send a man who is making transmission problems his special study. No obligation. Phone, wire or write.

A Simple Low-Pressure Steam Control Device

This Paper Read Before the Gloucestershire Engineering Society, Gained the First Prize for the Best Essay Written by an Associate Member of the Society.

By J. W. SMITH

FIGURE 1 shows a British Westinghouse mixed pressure steam turbine and electric generator; speed 2,500 revs. per minute; output of 368 kilowatts, at the Gloucester Wagon Company's central power station. It will give full output with either mixed pressure steam or high pressure steam only. It will give half output with exhaust steam chest at a pressure of 1 lb. per square inch. The high pressure steam enters the first expansion stage of the turbine through the steam chest "A," and the exhaust steam enters the last expansion stage of the turbine through steam chest "B." When working under mixed pressure conditions, that is, with both starting valves open, the governor throttle valves are arranged so that the exhaust steam does half load (if a full supply is available) and the high pressure steam does the balance of what the whole load may be. If the supply of exhaust steam diminishes, the governor automatically admits more high pressure steam; when more exhaust steam is again available, the governor admits less high pressure steam, keeping the generator output fairly constant while the supply of exhaust steam fluctuates considerably.

As supplied by the makers the machine was not complete, no provision having been made for automatically cutting off the last expansion stage of the turbine from the exhaust main, when the supply of exhaust steam failed. When the supply of exhaust steam fell below the quantity which could be passed by the low pressure starting valve, a partial vacuum was induced in the exhaust main (which is about 400 yards long), with the inevitable result that air was drawn in through some leaky joint or open drain cork. The starting valve could of course be regulated by hand to pass just the quantity of exhaust steam which was available, but, apart from occupying one man's whole time, this hand regulation was very troublesome and caused a waste of a lot of exhaust steam. The device described herein completely removed all serious troubles arising from fluctuations in the supply of exhaust steam.

A low pressure receiver, which diminishes the fluctuations in pressure of the exhaust steam from some steam hammers and non-condensing steam pumps, is outside the door shown in the background. After leaving the receiver the exhaust steam enters the low pressure chest through the pipe "C," then passing downwards through the starting valve and upwards through the emergency stop valve and the governor throttle valve into the turbine. A section of these two valves is shown in Fig. 2.

Before the control device was fitted, the driver had to stand by the low pressure starting valve and partially open or close it according to the pressure in the exhaust main, which is shown by one of the gauges on the panel behind the two steam chests.

The lift rod of the control device passes up through the floor plate "D," and the lever lies alongside the wall underneath. "E" is the handrail round the condenser pit. The driver used to sit on this handrail to watch the pressure gauge, and the lever was arranged so that the operating wire passed down just clear of his back. Only a small portion of the lever projects beyond the wall into the open condenser pit, so its somewhat ungainly length is not noticeable.

The steam control device, with the development of which the author was closely connected, was fitted to a mixed pressure steam turbine some eight years ago, and has given complete satisfaction ever since. The turbine was arranged to take the exhaust steam from steam hammers, hydraulic pumps and feed pumps. A large low pressure steam receiver was fitted a few yards away from it, which to some extent took up the fluctuations in the supply of low pressure steam, but it was found that the rate of supply varied so much that it was necessary to keep a man at the low pressure starting valve to avoid wasting steam, or, what was worse, drawing air into the turbine. The obvious re-

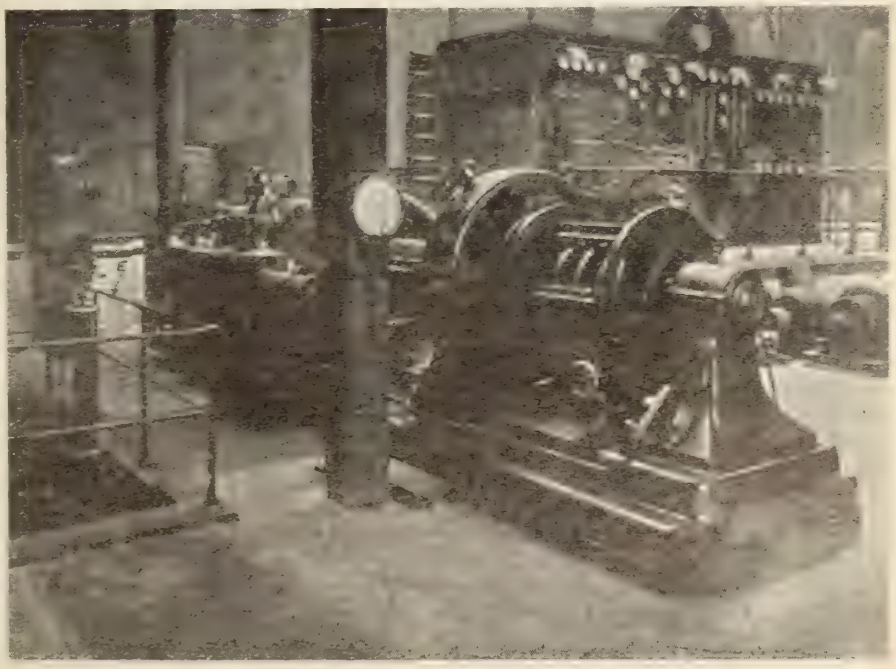

FIG. 1.

quirement was a very sensitive surplus valve which would shut when the pressure in the low pressure steam main was a little over atmospheric pressure, and would gradually open as the pressure rose, until it was full open when the pressure in the main reached 1 lb. per square inch. In connection with a somewhat unusual layout of boilers and steam mains the author had tested two high-pressure surplus valves, by well known makers, with such disappointing results that it was felt it would be useless to ask them for the very sensitive low-pressure valve required. The author's firm therefore decided to tackle the problem. The solution was staring them in the face, but the trouble to find it was much greater than would be supposed from a casual examination of the very simple gear which was evolved, and shown in Fig. 2. To an emergency stop valve normally lying idle in the turbine steam chest, we connected a float operated by a quantity of water lying idle in the steam receiver, and the job was done.

The turbine steam chest is fitted with an emergency trip stop "A" valve which closes upwards and whose spindle passes vertically through the bottom cover. This valve is of a piston type and is a duplicate of the governor throttle valve "B" fitted immediately above it. As arranged by the makers it was connected to its opening lever by a pair of short links "C." These links were replaced by some longer ones with a distance piece riveted between their ends to form a flat surface "D," and the bottom holes of the new links were elongated to allow the valve to be closed without raising the original operating lever. Under this against the wall of the condenser pit, was fitted a lever about 4 ft. 6 ins. long. At about 3 ins. from its fulcrum a vertical rod was jointed which passed through a suitable guide so that its end was just clear of the flat bottom of the new valve links, when the new lever was at the bottom of its travel. The end of the lever had to be raised about twelve inches to close the valve, and suitable guides and stops were provided to prevent all undue stresses. Owing to the 18 to 1 leverage provided, the effect of the friction of the valve and spindle was negligible at the end of the lever. The steam receiver "E," the shell of an old Lancashire boiler, had a syphon drain "F" connected to one end plate about 3 inches above the bottom of the shell. In consequence of the position of this drain there was always a quantity of water lying in the bottom of the shell, the surface of which measured roughly 3 ft. by 20 ft. At the other end of the steam receiver the old blow-off cock fitting "G" on the bottom of the shell had been blanked off. A 2½ in. cock was fitted to this blow-off cock branch one week end, and, working back from that the following week, we rigged up in a vertical position an old 7 ft. length of 8 in. cast iron pipe, and supported it from the floor by a length of 2½ in. pipe with a blank flange at the bottom. This pipe formed an excellent float chamber with sufficient head of water to seal the maximum pressure permissible in the receiver. Owing to the wide ratio between the surface of the water exposed to the steam on one leg of the submerged bend, and the surface of the water exposed to atmospheric pressure on the other leg of the submerged bend, about 60 sq. feet to 50 sq. inches, the rise of water in the float chamber was almost 2.3 ft. per lb. pressure in the receiver. A galvanized iron float was provided, 6 in. diam. by 12 in. deep, with a stretcher bar across its open top to enable it to be suspended correctly. This was filled with water and connected to the new lever by a flexible steel wire rope passing over two guide pulleys. Sufficient weight was then added to the lever to cause the float to be normally half submerged when the lever was clear of both stops.

The apparatus was now ready for a first trial. When the cock in the submerged bend was opened the pressure in the receiver was about 1½ lb. per sq. inch, and as the water rose in the float chamber the sag of the wire rope caused the light float to keep at the surface instead of becoming submerged. The float was then hauled out, a piece of rubber was spread over its bottom and sides, and about 3 lb. of iron punchings were put in as a make weight. An equal weight was added to the end of the lever and a second trial was made. This time the additional weight kept the wire rope taut and the float submerged if the water rose after the lever reached bottom (wide open) stop.

A curious fact in connection with the trip stop valve was now noted. This valve is of a piston type. It was assumed that it would not be affected by the pressure or the flow of steam and that its own weight would open it; it was found, however, that, while steam was passing through it, it would only open about an eighth of an inch when the new lever was depressed and that the lift rod then left the plain end of the valve links and travelled down without the valve. A slight pressure of the tips of the fingers was sufficient to open the valve, which rose again to its former position as soon as that pressure was removed. To get over this difficulty, that is to say, to enable the valve to be pulled open by the control gear and at the same time to avoid interference with its original function as an emergency valve, two pairs of spring clips were fitted to the top of the lift rod and were arranged to engage with slots in the edges of the links; as shown, enlarged, at "H"; two small cam washers were also fitted to the pin which passed through the original operating lever. As the new lever was depressed the spring clips now compelled the valve to follow it, and if the old lever rose the cam washers readily disengaged the spring clips from the valve links. The valve was thus enabled to perform in a very satisfactory manner both the work for which it was designed by the makers and the extra work for which it was desired to use it.

The steel wire rope used is about 3-32 in. dia. It consists of 42 strands of No. 34 s.w.g. wire and its breaking load is 560 lbs. Being very light and flexible it can be made to operate a throttle valve from a considerable distance. Recently a somewhat similar control device was fitted in which the throttle valve is operated, from a point over 150 yards away, by a similar flexible steel wire rope passing over 23 guide pulleys. The unbalanced pull on the wire rope when the lever is at rest, clear of both stops, is Zero. When the float is submerged, the lever presses with a force of 6 lb. on its bottom or "open" stop, and when the float is suspended in air through the water level in the float chamber falling below it, the lever produces a 6 lb. pull against its top or "shut" stop.

It is found that a displacement of only two inches of water above or below the centre of the float is sufficient to operate the valve, and that only a half pound variation of steam pressure is required to move the valve from "open" to "shut" or vice versa. It will thus be seen that a very simple solution of the problem was found. The value of this simplicity will perhaps be better appreciated when it is stated that the device has been in constant use for eight years and has not had a penny spent on it for repairs.

A part of the diagram is taken from a sketch supplied by the makers. It shows a portion of an end view of the turbine and a section through the valves in the low pressure steam chest. "A" is the emergency stop valve which is held open by the catch "I" while the spring "J" always tends to close the valve. The catch "I" can be knocked up by the driver in case of emergency, and it is knocked up automatically by a spring loaded trip bolt at the end of the rotor shaft if the turbine runs about 10 per cent. over speed. The other part of the diagram represents the steam receiver which is supported on piers about six feet above the floor level. It was raised above the floor partly to reduce the length of the steam pipes and partly to permit the introduction of the syphon drain "F" which is probably the most efficient form of low pressure steam trap in existence.

The exhaust steam from the hammers enters the receiver by the pipe "K" and passes out at "L" through a pipe which is not shown to the starting valve at the back of the steam chest. It then passes upwards through the two valves "A" and "B" and through a port which is not shown into the last expansion stage of the turbine.

The presence of the water in the receiver was entirely accidental. In preparing the diagram the author overlooked this point, but the end plate is flanged to fit inside the shell, consequently there is a considerable radius instead of the square end shown. When the syphon drain had to be connected to the receiver the fitter marked the hole just above this radius for convenience in drilling and tapping it.

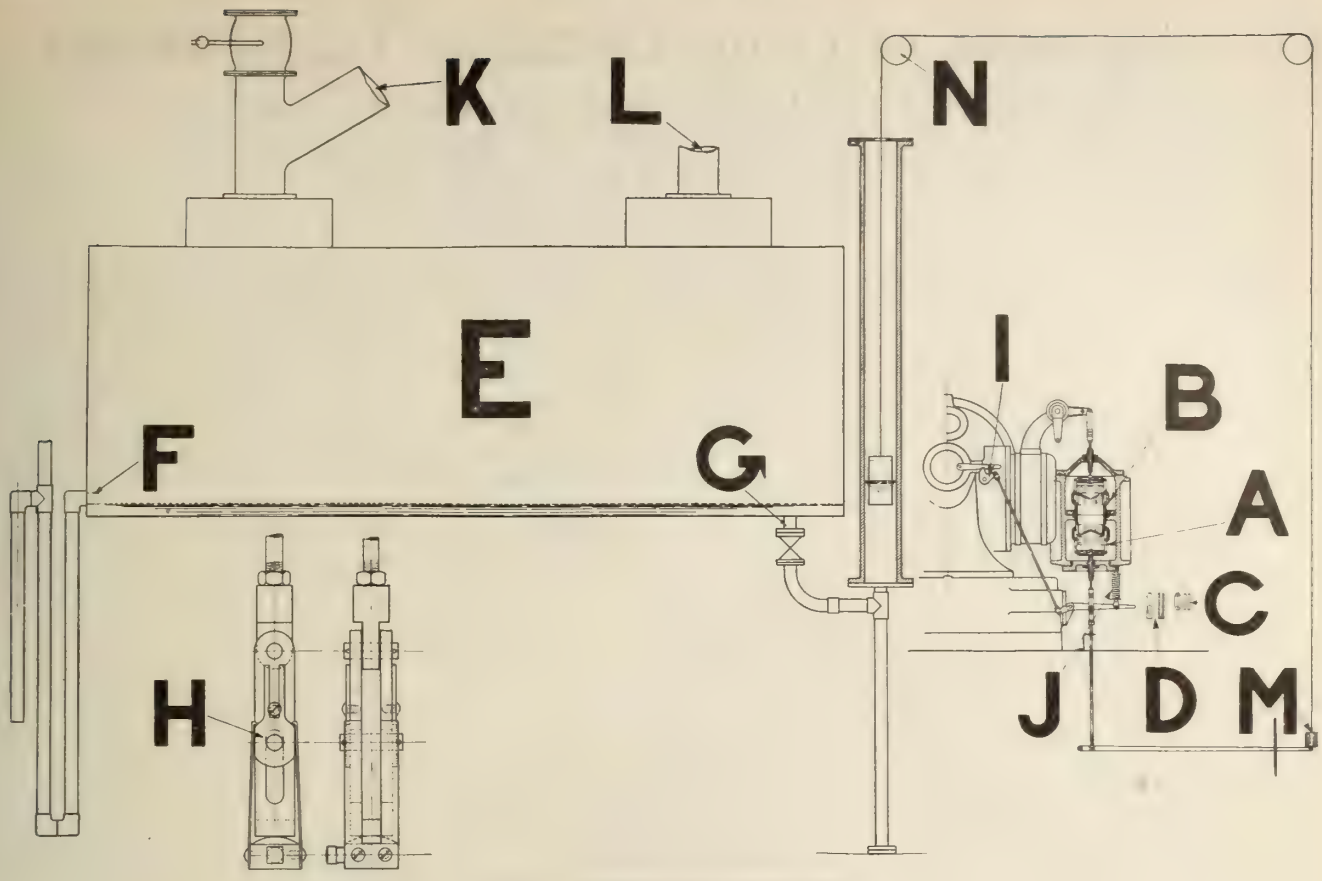

FIG. 2—DIAGRAM OF CONTROLLER.

It will be noticed that the middle of the syphon drain is long enough to seal about 3 lb. pressure and that the float chamber is long enough to seal rather more, also that an atmospheric relief valve is fitted to prevent this pressure being exceeded. It will be obvious, too, that neither the syphon drain nor the float control device can be conveniently used except at very low pressures.

Practically all variations of water level, due to pressure in the receiver, take place in the float chamber; one area of water is so large in comparison with the other that the slight variation of level which takes place in the steam receiver is entirely negligible.

In adjusting the weight "M" to cause the float to ride in the water half submerged, the pulley "N" was moved over a little so that the float could be lowered into a bucket instead of into the float chamber.

It was mentioned that the float failed to submerge when the water rose in the float chamber at the first trial. That was due to the sag of the horizontal wire between the two pulleys. The weight of the galvanized iron shell of the float is only about half a pound. The pull due to half a pound of iron submerged in water was not sufficient to keep the wire taut, but the pull of about three and a half pounds of iron submerged in water does it well. The float is always full of water, and the arrangement is capable of giving a six pounds pull in either direction at the end of the lever. This is a very liberal allowance for overcoming the slight friction at the various joints and wheels.

The fact that the flow of steam—the flow, not the pressure—will hold the valve "A" in suspension was quite a big trouble and nearly caused us to abandon the job. The simple little spring clips shown at "H" with the cam washers for releasing them, and especially the slotted projection and button-headed screw for keeping the cam washer upright, took the author fully a fortnight to evolve, and during that time the driver continued to perch on the handrail of the condenser pit like a huge sparrow, entirely destroying the harmony of the station.

Very slight fluctuations of pressure do not affect the float and there is always a small amount of lag in its movements. The water level has to be two inches above or below the centre of the float before it can overcome the inertia and friction of the gear, consequently under certain conditions within the range of this lever the pressure can fluctuate by an amount equal to 4 in. head of water without moving the float. Of course if the water rise after the lever reaches its bottom stop the float simply remains suspended under water, while if the water fall after the lever reaches its stop, the float simply remains suspended in air—nothing else happens.

The Sarco Company Inc., Woolworth Building, New York, are exhibiting steam traps, temperature regulators, recording gas calorimeters and CO_2 recorders, at the Chemical Exposition, New York.

The Sarco steam traps use the special Sarco tubular diaphragms and liquid expansion. They are claimed to be the only low price high-pressure type on the market and they cost about one third as much to make and market as traps of the ordinary bucket or float type.

The temperature regulators are specially designed for industrial purposes to regulate temperatures within a range of from 30 to 300 deg. Fahr., and are particularly suitable for chemical manufacturing operations, the canning industry, hot water service tanks, oil heaters, etc. The Sarco Company, Inc., although established only nine years, has made a very extensive study of temperature control for industrial purposes and has achieved a prominent position in this important and very promising field.

The Sarco recording gas calorimeter is of the type adopted by the Public Service Commission of New York. It burns gas in a finely regulated flame, the varying heat of which is recorded continuously in thermal units of the heat value of the gas. Gas engineering practice throughout the world favors the substitution of a heat value standard for a light standard for gas, and apparatus giving constant records is of great public as well as technical interest.

The Sarco CO_2 recorder gives a record of the carbon dioxide in flue gas from boiler furnaces. The percentage, subject to a few simple rules, is a definite indication of furnace efficiency and tells whether fuel is burned to advantage or to waste.

Development of Long Distance Transmission

In This Lecture Delivered Before the Johns Hopkins University as One of the John Aldred Lectures the Progress of Electrical Development is Reviewed from 1876 to Date.

By PAUL M. LINCOLN, Consulting Engineer, Cleveland

IN taking up such a subject as that to which I am to address myself this afternoon it is proper, first, to call attention to the extent of use to which electricity has attained in our modern life. Electricity is used in thousands of ways by the present-day human beings, and its use has had a marked influence upon the development of the present-day civilization.

It is doubtful, for instance, if our modern cities could have come into being without the aid of electricity. The modern city is typified by the congestion into a relatively small area of exceedingly large numbers of human beings, who each day must go and come to and from their daily work, be fed, clothed and generally ministered to for their infinite variety of daily wants. In all of these ministrations electricity has come to assume so important a part that I believe it is a safe assertion to say that without electricity our modern cities would be very different from what we find them today.

Take, for instance, the one item of transportation. Transportation is, of course, essential to our modern life, and with the rapid growth of our cities and the consequent congestion of large numbers of human beings into a relatively small space, the complexity of the transportation problem has increased to such a degree that it is doubtful if any other than electrical method of transportation could have solved the problem. The modern subway is made possible only by the use of electricity, and without the subway such cities as, for instance, the city of New York as it now exists would be impossible.

Not alone in transportation has electricity proved itself indispensable to our modern life, but in many other ways. For instance, as a source of light it is well nigh indispensable to take care of the congestion of large numbers of people into relatively small buildings such as we find in our modern cities. But its usefulness does not stop here. It ministers to us in thousands of ways. New duties are being found for it every day. In the household it assists the housewife; it cooks the meals, it washes and irons her clothes, it operates the refrigerator, it sweeps the floors and furnishes a cooling breeze that may make endurable an otherwise unendurable condition.

In industries its influence is even more important. Power is an essential to the modern industry. Power is as essential to our present-day industry as the air we breathe; it is absolutely indispensable.

In this matter of power and its influence on the industry, particularly in modern times, I think it is only proper to quote from a book—The New Epoch—written by Mr. George S. Morison, a noted civil engineer. This book was written more than twenty years ago, and the developments of the past twenty years have only confirmed the analysis and deductions made by Mr. Morison in his book. In this work Mr. Morison has pointed out the means by which man has progressed from a mere animal to his present position. In his rise from the condition of the beast the first thing that man acquired was the use of fire. This knowledge differentiated him from the beasts that surrounded him, and while still a savage, he was better off than the beast.

The second tool that man acquired in his climb from the condition of the beast to his present position was the use of the bow and arrow, and with its use another epoch began. With the invention of pottery and all that this implies—cooked food and greater permanence in place of residence—another epoch began and man passed out of the state of savagery and made a distinct advance toward the state of civilization. Still another epoch began when he acquired the ability to domesticate animals. He was thereby enabled to use a power beyond that of his own body and muscle. This ability gave him a distinct advantage. The final epoch of the savage or barbarous period began with the manufacture of iron, and finally with the acquisition of the written alphabet an epoch began which we now recognize as the epoch of civilization. With the ability to pass on the knowledge of one generation to the next, which the written language gave him, man acquired a power that was vastly important. I think I can do not better than to quote Morison's own language in further illustration of his points:

"The changes which mark the advances from period to period are all material improvements; in every instance they are characterized by some distinctive physical device which has enabled man either to utilize his own strength better than before, or to increase his power by adding other animate or inanimate force. The race that passed from one period to another acquired resources which it had not before: in the contests which characterized the life of primitive man, the men of a lower period fell before those who had risen higher. But though the devices were of a purely material character, they gave opportunities for mental and moral improvement which alone made further advance possible, till finally the written alphabet resulted in that preservative of knowledge which has made the intellectual efforts of thirty centuries available for ourselves. With the dawn of civilization the ethnical periods have been considered closed; subsequent growth has been the natural advance of civilization marked by the events which make written history.

"But there is no reason why the epoch which began with writing should be the last. It only needed a new capacity, radically unlike those which have gone before, to make an epoch in civilization as distinct as those in primitive society. Such new capacity has now been found; another epoch has begun. Fire, animal strength, and written language have in turn advanced men and nations; something like a new capacity was developed with the discovery of explosives, and again in the invention of printing; but the capacity of man has always been limited to his own individual strength and that of the men and animals which he could control. His capacity is no longer so limited; man has now learned to manufacture power, and with the manufacture of power a new epoch began. These words are used advisedly; creation, whether of substance or force, is not given to man; manufacture is not creation, but to change inert matter from one form to another in such a way as to generate power is to manufacture power. And this we do."

While I agree entirely with Mr. Morison in his analysis of the influence of power upon the development of the human race, I wish to point out that it is the electrical engineer, we ourselves, who have made its complete realization possible. The production of power is of itself not sufficient to bring about the new epoch which Mr. Morison has portrayed to us. To bring about the complete realization of this new epoch, power must not only be produced, but must be made available at points convenient for the use of mankind, in the household, in the shop, in the office; in fact, wherever man is he may need to use this power, and if we would realize to the full the benefits of power we must make it universally available. It is the electrical engineer who has made this realization possible by his ability to transmit and distribute power by means of electricity. It is my object in this brief address to set before you a brief history of the manner by which we have come to possess the knowledge and experience by which in turn we can today so easily transmit and distribute electrical energy.

An historical sketch of the develop-

ment of electricity usually begins with the amber of the ancients and passes in review the contributions of the various scientists to our knowledge of electricity. Such names as Gilbert, Volta, Ohm, Oersted, Ampere, Franklin, Davy, Faraday, Henry, Morse, Bell and many others, together with the labors and discoveries of each, might be set forth in detail. While this method may be interesting, it is already available in many historical reviews which have been written on the history of electricity. While the pure scientist, that is the man who seeks knowledge purely for the sake of knowing, is entitled to the utmost credit, the art of transmission and distribution of electricity as it is recognized today is an "applied" science, and it is the history of electric transmission and distribution as a commercial enterprise that attracts our attention first; it is this phase of the historical review to which I wish to draw your particular attention tonight.

Aside from the telegraph, the first commercial application of electricity was for lighting, and the first commercially successful electric lighting enterprise was that of an American, Charles F. Brush, of Cleveland. It was in 1876 that Brush produced his first successful dynamo-electric machine for the production of an arc-lighting system. At the time Brush began his work there was neither lamp nor dynamo—at least not in commercial form, and he had to attack the problem from both of these standpoints and solve not only the problem of the dynamo to produce electricity, but also the lamp in which the electricity was to be used to produce light. At the time Brush attacked this problem of electric lighting there were no commercially successful lighting systems. There had been produced a few isolated instances where electricity had been used for illumination, but these were isolated instances and were in no case successful from a commercial point of view. Brush, therefore, had a clear field before him. The attempts of Brush in the development of both the arc lamp and the dynamo to operate it were entirely successful. As indicated above, his first success was attained in the year 1876. The first lighting outfits which he made required the use of a separate dynamo for each lamp. Soon, however, Brush conceived the idea of operating his lamps "in significant series" so that the current from one passed in series to the next, and then to the next, and so on. At first the number of lamps operated in series was small, but later, as experience accrued, the number increased until, in some of his later machines, voltages in excess of 5,000 were common. The fact that Brush devised a series rather than a parallel or multiple connection for the purpose of operating more than one lamp from one machine had an important influence on the development of the art of transmitting and distributing electrical energy. This will be further developed as we proceed.

Although the first successful experimental arc machines were produced by Mr. Brush in the year 1876, the success of his enterprise as a commercial venture was not assured until about 1878. Beginning in 1878, Mr. Brush and the Brush Electric Co., which he formed and operated from that time on, proved highly successful from a commercial point of view. The Brush Company installed arc lighting outfits in many cities, towns and villages, and the success of his enterprises from a commercial point of view was complete.

By the year 1880 the commercial success of the Brush Company and its arc lighting system had become so pronounced that the industry began to attract competitors. One of the first American competitors to enter this field was the Thomson-Houston Company, of which the moving spirits were Mr. Elihu Thomson and E. J. Houston. These men developed both a dynamo and a lamp to compete with the one which Brush was using at that time. While there were a considerable number of detailed patents taken out during this period on both lamps and dynamos, there was nothing of sufficient fundamental importance to enable either the Brush Company or the Thomson-Houston Company to cover the method of arc lighting sufficiently to exclude competition. From then on the arc-lighting business continued to attract a considerable amount of attention, and still other companies entered the field. It is hardly necessary in this brief review to detail each of these companies, but it is important to point out that all companies used exactly the same method of distributing the electricity used for arc lighting as Brush previously had devised in 1876. While this method served very well for arc lights, it did not form the basis of the method of transmission and distribution of electrical energy in use today. This method did not come until later.

There was one outstanding objection to be noted in the arc-lighting systems, and this was that the unit of light was too large for convenient use indoors. While the arc lamp was made a very good street-lighting outfit, the light was so brilliant and so large an amount in a single unit that it was not applicable for indoor illumination. The problem of the day, therefore, was the so-called "divisibility" of the electric light. Among others, this problem was attacked by Mr. Thomas A. Edison, and in 1879 Mr. Edison produced his "incandescent" lamp. This "incandescent" lamp was built on an entirely different plan from the arc lamp of Brush, and constituted a very important advance in the electric art of that day. It accomplished the "divisibility" of the electric light, which was recognized as the foremost problem of the day. Edison's solution of this problem was one of the most brilliant achievements of modern times, and he is justly hailed as the foremost inventor of his age, and this largely on account of his accomplishments in the field of electricity.

It should be pointed out that Brush and Edison were working along two very different lines in so far as the method of distributing electricity was concerned. In Brush's arc-lighting system he used the lamps in series, and the same current passed in series from lamp to lamp. The voltage across one lamp was in the neighborhood of 45 to 50 volts, and each lamp in a circuit added its quota to the total voltage of the circuit. When, for instance, 50 lamps were used in series in one circuit, the total voltage across the entire 50 lamps approached something of the order of 2,500 volts, while the amount of current both in the dynamo and at any point in the lighting circuit was always the same, viz: about 9½ to 10 amperes. Edison attacked the problem of distributing his electricity on a very different principle. Instead of placing his lamps in series, as was the case with Brush, he placed his lamps in parallel, the voltage applying to the entire circuit being the same, each lamp adding its quota of current to that of the others. The method of distributing power was, therefore, fundamentally different in the case of Edison from that in the case of Brush, and this difference was to have a far-reaching effect in the development of electric power transmission and distribution.

Edison had to attack the problem not only of producing a lamp, but also of producing a dynamo to operate his lamps, and then of producing a distributing system for the purpose of taking the electricity from the dynamo to the lamps. There were, therefore, at least three problems which Edison had to solve—not one. Although Edison's first successful experimental lamp was produced in 1879, the other problems, that is, the problem of production of the dynamo and the problem of a distribution system, were not sufficiently advanced for nearly three years to enable him to put into operation an entirely successful electric lighting system. However, Edison persisted in his attempts to produce such a complete system, and in the year 1882 the first successful central station electric lighting system went into operation. The honor of the first successful Edison system goes to the little town of Appleton, Wis. This was followed a few weeks thereafter by the starting up of the well-known "Pearl Street Station" in the downtown part of New York City. The Pearl Street Station of the New York Edison Company operated for many years thereafter and has long been pointed out, not only as one of the first successful central stations, but also as the beginning of one of the most successful commercial enterprises of modern times.

Edison's achievement in producing first the incandescent lamp, second, the dynamo, and third, the distributing system for the taking power from his dynamo to his lamps, is to my mind one of the most brilliant achievements that has

ever been accomplished in the electrical field. He is entitled to the utmost credit for persevering under the many discouragements which he met in carrying to completion his great work in those early days. Edison's name is connected with many epoch-making inventions, but none of them shed more lustre on his name than does the electric lighting industry, so many units of which so appropriately bear his name.

In this connection it might be pointed out that the only use of electricity at this early date was for lighting. The use of electricity for power had not been seriously thought of. This is indicated clearly in the names of the various companies going into electrical enterprises in those early days. The term "Electric Lighting Company" was universally used for electrical enterprises in those days. The term "power" in connection with such enterprises was not used until many years after Edison started his first electric lighting system.

This was not because the ability to use the electric dynamo or generator as a motor was not known. This ability to use the electric generator as a motor was well known in the early days. In fact, it was as early as 1837 when the "reversibility" of the electric dynamo was discovered. But the first commercial use to which electricity was put was for lighting, and for many years lighting was its only commercial use. Then followed a period when electricity began to be used for power, but its use as a source of light rather than power was still predominant. As time went on lighting came to have a smaller and smaller relative importance in electrical enterprise until today the use of electricity as a source of power far overshadows its use in lighting.

During the decade from 1876 to 1886 the electric lighting industry developed tremendously. During the first five years of this period the development was entirely along arc lighting lines. With the advent of the Edison incandescent lamp in 1879, and the Edison dynamo and distributing system in 1882, a new method both of lighting and distributing electricity came into vogue. But neither the Brush nor the Edison method of distribution had within it the germ of a success as a complete transmitting and distributing system as we know that term today.

It should be emphasized again that these two systems were entirely different, one being constant current—variable potential—that of Brush—and the other being constant potential, variable current—that of Edison. The system as advocated by Edison lent itself to power distribution more readily than did that of Brush. This came about on account of the fact that the motors for use with the current which Brush was producing for the arc lighting dynamo could not be readily governed so far as speed was concerned. Motors, when operated from a constant variable potential source required a special kind of generator in order to make them regulate properly in the matter of speed. This restricted the use of motors when operating from that source to a very considerable degree. While this disadvantage was recognized, it was also recognized that in the matter of transmission the system which Brush had been using had a very considerable advantage in that the voltage that it carried was very much higher than that which Edison was able to use. The increased voltage gave the Brush system a very considerable advantage in the matter of the amount of copper conductor required to carry a given amount of power over a given distance. The series system of Brush was used to some extent, or rather an endeavor was made to use it for power purposes, but it did not meet with any very large degree of success. During the late eighties a copper mine in the Lake Superior copper district was equipped with a Brush dynamo and Brush motors, but their success was not sufficiently marked to indicate that it would have a very brilliant future.

Still another attempt to use the Brush method of generation and distribution of electricity during the eighties is worthy of note, as indicating that the problem of transmission was receiving careful attention. I refer to the endeavor of Sidney H. Short to develop the so-called "Short Series System" of railway operation during the late eighties. Short early recognized the difficulties that would be encountered if the Edison system of distribution was to be used to handle the relatively large amounts of power required by railways. He, therefore, devised a method of operating street railway cars so that all cars would at all times be in series—just as is the case of the Brush system of arc lighting. An attempt was made to put this system into operation in the city of Denver, Col., about the year 1886, and another attempt was made in the city of Columbus, Ohio, in the year 1889. Both these attempts were failures, and the complete success of Sprague with a modified Edison system of distribution in Richmond in 1887 caused Short to give up his attempt to develop the series system. However, let us give Short the credit of recognizing that the transmission problem was paramount and of at least trying to solve that problem along novel lines.

During the period from 1880 to 1885 the electric lighting industry developed by leaps and bounds. This was true not only of arc lighting with the Brush Company and the Thomson-Houston Company, as its principal advocates, but also it was particularly true of the Edison Company, as well as its competitors, which began to appear as soon as success was assured. It is only proper to point out again that neither of these systems was capable of development to a degree that could be called successful, as we know that term today. The art of transmission and distribution of electrical energy, as we know it today, requires ability to transmit quantities of power and over distances which are totally outside of the range of the systems which were adopted and used for electric lighting systems between the years 1880 and 1885. In the first place, the systems adopted by Edison were limited to comparatively low voltages. Edison started with the idea of using approximately 100 volts on his lamps. He soon recognized that this was not a sufficiently high voltage for distribution, even over the areas usually required in a normal city, and as a consequence, developed his "three-wire system" of distribution, in which the voltage doubled. The three-wire 110-220 volt system thereupon became the standard method of distribution for cities in the United States, and to a degree has remained so ever since.

In the second place, the system which was developed by Brush and his imitators was not capable of being developed into a general power distribution system—as we know that term today—for the reason that it was impossible to eliminate the element of danger due to high voltage from the method of distribution as soon as any considerable amount of energy was demanded. Incidentally, also, the inherent difficulties of operating motors and incandescent lamps on the Brush constant current circuits were much greater than with the Edison constant voltage system. Therefore, neither of the systems of distribution in use up to the year 1885 contained the germ of success for long-distance distribution of electric energy, as we know that art today.

It was the invention in 1883 of the "alternating current transformer" which gave the first hope of success for the system of transmission and distribution of electrical energy as we know that art today. The transformer was invented by a Frenchman named Gaulard, and an Englishman named Gibbs. The transformer was a development from the Ruhmkorf coil, which had been known for a number of years. It was during the year 1883 that Messrs. Gaulard & Gibbs disclosed their transformer. An account of this transformer came to the notice of Mr. George Westinghouse of Pittsburgh in 1885, and with this notice the era of transmission of electrical energy may be said to have begun.

At that time Mr. Westinghouse was already a marked figure. Sixteen years previously he had invented the air brake and had made not only a brilliant engineering success of that invention, but a brilliant financial success as well. But the air brake was only one of the many inventions which Mr. Westinghouse promoted. The transmission and distribution of natural gas was a subject upon which he had been devoting much attention during the period from 1880 to 1885. His ideas for compressing gas to high pressure for transmission over long distances and then reducing that pressure to a much lower point for distribution throughout a city had already taken form, and it is not unlikely that it was the analogy between the Gaulard and

Gibbs transformer and his own gas transmitting method that attracted him particularly to that idea. For several years previous to 1885 Mr. Westinghouse had been conducting experiments along electrical lines. He had been following the Edison method of generation and distribution, and had distinctly recognized both the shortcomings of the low voltage that Edison was using, as well as the danger attached to the high voltage, made necessary by the method of Brush. He recognized at once that the Gaulard & Gibbs transformer—if it were a success—would at once avoid both these difficulties. That Mr. Westinghouse recognized the great possibilities of the transformer is indicated by the fact that at once he dispatched an agent to Europe with instructions to purchase the Gaulard & Gibbs patents, no matter what the cost.

In the year 1883 Mr. Westinghouse had come in contact with Mr. William Stanley of Great Barrington, Mass. Mr. Stanley was also working on electrical matters, and Mr. Westinghouse put up to Mr. Stanley the problem of making the transformers into a practical device which could be used in the electric lighting industry. Apparently Messrs. Gaulard and Gibbs, in obtaining their patent on the transformer had the idea of using that device in a manner similar to the method in which Brush was distributing electricity to his arc lights. That is, the various transformers were connected in series, the primary current passing from one transformer to another, and the secondaries of these transformers were to be used for actuating the lamps or other devices. Apparently, the principal idea which Messrs. Gaulard and Gibbs had in mind was the avoidance of the danger to life which the arc lighting systems of that day entailed. By putting in transformers and operating lamps or other devices from the secondaries of these transformers the high potential of primary arc lighting circuit could be avoided and thereby the lamps or other devices made safe. It was apparently the Brush method of transmitting and distributing electricity that Gaulard and Gibbs had in mind when they devised their transformer, not the Edison method.

Mr. William Stanley at once recognized the serious shortcomings of this proposition of Messrs. Gaulard and Gibbs. He recognized, also, that it was possible to use transformers on a constant potential, variable current system similar to that which Edison was using, instead of the constant current, variable potential system which Brush was using. It was in the year 1886, and in the town of Great Barrington, in the western part of Massachusetts, that Stanley first used the alternating current transformer in the manner in which it is commonly used today. A short section of relatively high voltage, constant potential transmission line was operated in that town in March of the year 1886, and transformers were used to step down this high voltage to constant potential incandescent lamps operated on the secondaries. Thus, it was in March of the year 1886, in Great Barrington, Mass., that the first transmission of electricity by alternating current took place. While this in itself was an unimportant application, it had within it the germ of success for the alternating current distribution of power and light as we know that system today. Every element that today gives us the ability to transmit power over distances running up to hundreds of miles, and in quantities of hundreds of thousands of kilowatts, existed in that small experimental line first put into use in the year 1885 in Great Barrington. Modifications have, of course, taken place in frequency, in phase, in voltage and in distance of transmission, but these modifications are simply of degree, not of kind.

During the years 1885 and 1886 Mr. Stanley continued his investigations under the inspiration and at the expense of Mr. George Westinghouse in the city of Pittsburgh, and in the fall of 1886 the famous Lawrenceville experiment took place. In that experiment several hundred lamps were operated successfully in the little suburb of Lawrenceville, the source of power for those lamps being an alternator located in the old Garrison Alley Works of the Westinghouse Electric and Manufacturing Company, about two miles distant. The operating voltage of that transmission line was at first 1000 volts, and this was later increased to double that amount, or 2000 volts. During the earlier experiments the voltage on the lamps was 50 volts. This was later increased to approximately 100 volts. Transformers were used to step down the line voltage of 1000 or 2000 to the 50 or 100 volts on the lamps. Thus, in Lawrenceville, in the year 1886, an experiment in the transmission of power by alternating current was carried on which confirmed entirely the first experiences of Stanley in Great Barrington some months earlier. The success of the Lawrenceville experiment was complete, and the Westinghouse Electric Company, which had been organized in 1886, began the commercial exploitation of electric lighting equipment, incorporating this new idea of alternating current generation and distribution. The Westinghouse alternating current system began to be exploited commercially, therefore, in the year 1886, and during the next two years about 200 central station plants using this alternating current method of distribution were installed in the United States. The first one of these plants was installed in the little town of Greensburg, about thirty miles east of Pittsburgh. The second went into the city of Buffalo, N.Y. Both of these plants were installed during the latter part of the year 1886, and as indicated above, during the succeeding two years the systems attained very great popularity, some 200 being installed during the first two years.

At the time of its inception there seemed to be no prospect of using the alternating current system for anything but lighting. The alternating current motor had not yet arrived. It was not until the year 1888 that Nicola Tesla patented his "induction" motor. Although Tesla's original patents were issued in the year 1888, there was nothing commercially tangible from this idea until nearly five years later. I consider the conception of the alternating current induction motor by Nicola Tesla as one of the most brilliant conceptions that has ever taken place in the field of electrical development. Tesla was essentially a dreamer, and the road from the dream to the reality was a long and tortuous one. In the first place, all alternating current systems installed up to that time had been single phase, and consequently were not available for the polyphase motors that Tesla had devised. In the second place, the task of turning Tesla's brilliant conception into an actual working device was not a simple or easy one. This work was done by a group of brilliant engineers in the employ of Mr. Westinghouse, and it was in this period that a number of well-known names were first mentioned. Mr. Albert Schmid, of revered memory, was one of these pioneers who had a decided influence upon the electrical industry at this time. Others who are well known who did much towards developing the Tesla motor, and the auxiliary equipment which it necessarily brought with it, were Mr. O. B. Shallenberger, Mr. R. Bellfield, Mr. Charles F. Scott, Mr. L. B. Stillwell, Mr. B. G. Lamme and Mr. R. D. Mershon. As I indicated above, it required nearly five years from the time of the conception of the induction motor until a commercially successful alternating current "power distributing system" was placed on the market. The lapse of time was not entirely due to the development of the motor alone. It was largely due to the fact that up to this time electricity as a source of power was then considered entirely of secondary importance. As a consequence, up to the year 1889, or 1890, none of the alternating current systems which had been installed were of anything except the single phase variety. The induction motor being a polyphase motor and not being adaptable for use on single phase circuits, was, therefore, not adapted to use on any of the existing alternating current systems at that time. As a consequence, a new system of generation and distribution had to be developed and put into use before the new type of motor could be extensively used.

The polyphase generator and the polyphase distribution system did not attain a vogue of any noticeable degree until about 1892 or 1893, and at that time the polyphase motor, having been placed upon a basis where it was recognized as a successful device, the polyphase system, including, of course, the polyphase motor, began to come rapidly into general use.

A Course of Instruction for the Graded Certificate

We Will in This Course Go Through the Mathematical and Theoretical Work to Cover Every Grade of Certificate Issued by the Ontario Board

By T. H. FENNER

HAVING studied the method of calculating the various types of riveted joints used in building boilers, we can now return to the boiler we were considering in earlier articles. This was to be a 100 horsepower boiler at the standard rating of 34½ lbs. water evaporated from and at 212 degrees. We arrived at the leading dimensions, which were 72 inches diameter and 18 feet long, with a working pressure of 125 lbs. per square inch. We can now proceed to find the necessary thickness of shell to carry the required steam pressure.

We saw when studying the bursting pressure of a sphere that the result arrived at was that f, the stress, was equal to the pressure multiplied by the diameter and divided by twice the thickness or, expressed as a formula,

$$f=\frac{pd}{2t}$$

When we wish to apply this to an actual boiler, we have some variations to introduce, these being the least percentages of longitudinal joint, and the factor of safety. Neglecting these for a moment, we will show how to find any one of the factors from the others. For instance, to find the pressure the formula would be

$$p=\frac{f2t}{d}$$

To find the thickness we would have

$$t=\frac{pd}{2f}$$

While to find diameter the formula becomes

$$d=\frac{2tf}{p}$$

The formula to find the working pressure of a boiler is

$$WP=\frac{S\times\%\times2t}{d\times F}$$

where S = tensile strength of material, % = least percentage of longitudinal joints, t = thickness of plate in inches, d = diameter in inches, and F = factor of safety.

We have already set the required working pressure, and as we are to get a boiler of good workmanship and material we can assume 4.5 as a factor of safety. We will use a triple-riveted double-strap butt joint with an efficiency of 86% for the longitudinal seams, so that all that remains is to find the required thickness of shell. We must, therefore, substitute the known figures in the formula, and thus find the unknown. We have then

WP = 125,
d = 72,
S = 60000,
F = 4.5,
% = 86.

Putting in the figures, we get

$$\frac{60000\times.86\times2t}{72\times4.5}=125.$$

It is easier to use all fractions instead of decimals, so

$$\frac{60000\times86\times2t\times2}{72\times100\times9}=125.$$

By cancelling out we get

$$\frac{50\times86\times2t}{3\times9}=125$$

$$2t=\frac{125\times27}{50\times86}$$

$$t=\frac{125\times27}{100\times86}$$

$$t=.3924.$$

The nearest fraction to this is 25-64, but as the plates are not made in variations closer than 1-32, we will call it 3-8 inch and see if that will give the desired result. If not, we will increase it 1-16.

Then

$$\frac{60000\times86\times2\times3}{72\times100\times9\times4}=WP.$$

Cancelling

$$\frac{50\times86}{9\times4}=119.$$

This gives only 119 lbs., so we must take 7-16 as the size of plate, and try again.

$$\frac{60000\times86\times2\times7}{72\times100\times9\times8}=WP.$$

Cancelling

$$\frac{25\times43\times7}{6\times9}=139.$$

This gives us 14 lbs. more than we require, but as plates in this country are not rolled to dimensions of thirty-seconds of an inch, we must use the 7-16 plate. This is a good fault, as it allows a margin against corrosion, and makes practically no difference to the heat conductivity. It also allows a bigger factor of safety. This will now be, assuming the pressure is carried at the figure first set

$$\frac{60000\times86\times7}{72\times100\times F\times8}=125.$$

Then

$$F=\frac{60000\times86\times7}{125\times72\times100\times8}$$

Cancelling

$$F=\frac{86\times7}{5\times24}$$

$$F=5.$$

Designing the Joint

We have now got the diameter, length and thickness of plate of the boiler, and now we will determine the particulars of the joint.

First, as we have seen in the articles on riveted joints we will determine the pitch of rivets in the outer row. Then

$$\frac{P-D}{P}=.86$$

$$P-D=.86P$$

$$D=.14P.$$

Now we have 7-16 plate, we will have a 15-16 inch rivet, and if the diameter is .14 of the pitch, the pitch will be

$$\frac{.9375}{.14}=6.69 \text{ or say } 6\ 11\text{-}16.$$

Let us see how close this will come to the required percentage.

$$\frac{6.6875-.9375}{6.6875}=85.98\%.$$

This is sufficiently close for all purposes. We will now try the rivet strength, using the pitch found. We

shall have four rivets in double shear and one in single shear, making eight rivet areas in all. Then by formula, using .7 as the constant for steel rivets in steel plates

$$\frac{a \times n \times C}{p \times t} = \%.$$

Then

$$\frac{15 \times 15 \times .7854 \times 8 \times 70 \times 16 \times 16}{16 \times 16 \times 107 \times 7 \times 100} = \%.$$

Cancelling

$$\frac{9 \times .7854 \times 20}{107} = 132\%.$$

This gives a much higher percentage of rivet strength than plate strength. By reducing the rivet diameter to ⅞ inch we get a higher plate strength, and a lower rivet strength, thus

$$\frac{7 \times 7 \times .7854 \times 8 \times 70 \times 16 \times 16}{8 \times 8 \times 107 \times 7 \times 100} = 111.3\% \text{ rivets}$$

and $\frac{6\ 11\text{-}16 - ⅞}{6\ 11\text{-}16} = 86.9\%$ for plate.

This is more in proportion, and the smaller size rivets will reduce the cost of manufacture.

We will now see if we are within the limits of the maximum pitch as allowed by the Ontario regulations. The maximum pitch is found by using the formula

$$PM = (C \times T) + 1⅝$$

where PM = maximum pitch,
C = Constant,
T = Thickness of plate in inches.

The constant C varies with the type of joint as follows:

No. of Rivets in one pitch	Constant for Lap joint	Constant for Double butt Strap joints
1	1.31	1.75
2	2.62	3.5
3	3.47	4.63
4	4.14	5.52
5	....	6.00

As there are five rivets in a pitch, we must use the constant 6. Then

$$PM = (6 \times .4375) + 1.625$$
$$= 2.6250 + 1.625$$
$$= 4.25.$$

Although the regulations omit to state this, in a joint with every alternative rivet omitted in the outside row, this formula should be multiplied by 2, and in this case the maximum pitch for the outside rivets is therefore 8¼ inches, and we are well inside this dimension. The combined efficiency of plate and rivets must be found from the formula given in the regulations:

$$\frac{(A \times C) + (P - 2d)T}{P \times T}$$

This, as can be readily seen, is the shearing strength of one rivet, multiplied by the constant, and added to the net section of the plate between the outside row of rivets, divided by the unit section. Substituting figures we get

$$\frac{\left\{\frac{7 \times 7 \times .7854 \times 70}{8 \times 8 \times 100}\right\} + \left\{6 - \frac{11}{16} - 1¾\right\} \times \frac{7}{16}}{6\frac{11}{16} \times \frac{7}{16}} =$$

Combined Efficiency.

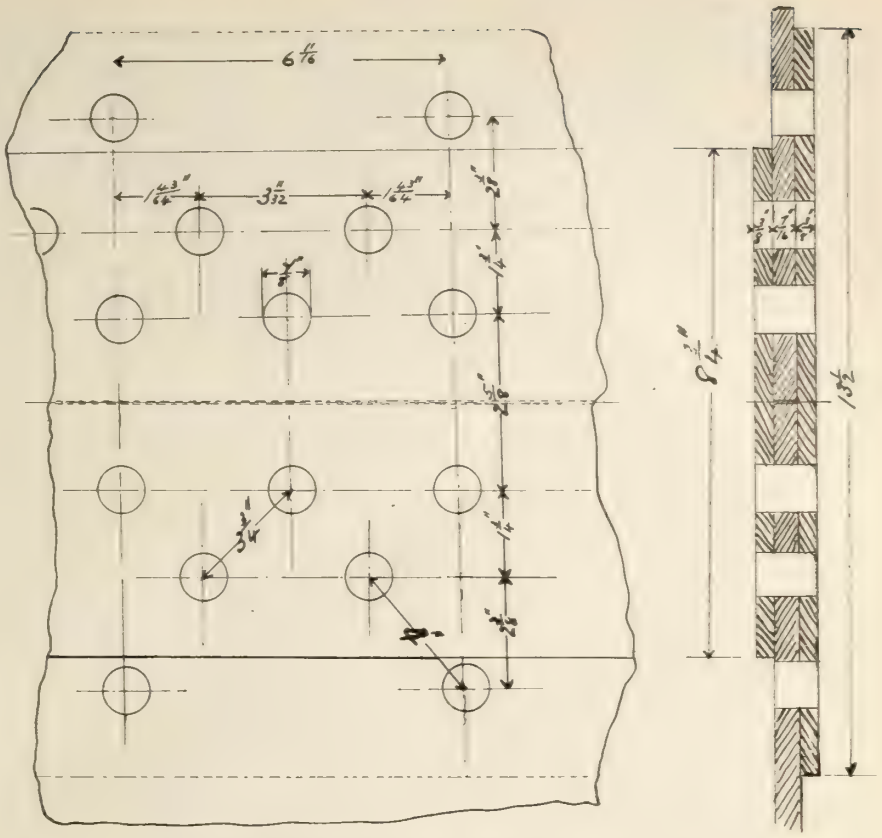
Reducing to decimals it becomes

$$\frac{.42 + 2.16}{2.92} = \frac{2.58}{2.92}$$

$$= 88.3\%,$$

which is higher than the plate strength as determined.

We must now determine the distance between the rows of rivets, and the exact allowable arc definitely decided by the regulations. Of course one could arrive at this distance by calculating the section of metal to be left to secure the necessary strength, but for the purpose of those passing examinations it will be better to work out the formulae set down by the Ontario board. The minimum distance between the outer and middle rows is found by the following expression, where V = the minimum distance:



TREBLE RIVETED DOUBLE UNEQUAL STRAP JOINT.

$$V = \sqrt{[(11\text{-}20P + d)(1\text{-}20P + d)]}$$

In order to make these clear we will show the various steps in full. Substituting figures we get

$$V = \sqrt{[(11\text{-}20 \times 6.6875 + .875)(1\text{-}20 \times 6.6875 + .875)]}$$
$$= \sqrt{[(.55 \times 6.6875 + .875)(.05 \times 6.6875 + .875)]}$$
$$= \sqrt{[(3.6781 + .875)(.3343 + .875)]}$$
$$= \sqrt{(4.5531 \times 1.2093)}$$
$$= \sqrt{5.4793}$$
$$= 2.33$$

Therefore 2.33 inches is the minimum distance between outer and middle rows. For the distance between inner and middle rows we have

$$\sqrt{[(11P + 8d)(P + 8d)]} \div 20$$

Substituting figures

$$\sqrt{[(11 \times 6.6875 + 8 \times .875)(6.6875 + 8 \times .875)]} \div 20$$
$$= \sqrt{[(73.5625 + 7)(6.6875 + 7)]} \div 20$$
$$= \sqrt{[80.5625 \times 13.6875 \div 20]}$$
$$= \sqrt{[1102.69 \div 20]}$$
$$= 33.2 \div 20 = 1.66.$$

Then 1.66 inches is the minimum pitch between the inner and middle row.

For the minimum diagonal pitch between inner and middle rows the formula is

$$P = (3P + 4d) \div 10$$
$$= (3 \times 6.6875 + 4 \times .875) \div 10$$
$$= (20.0625 + 3.5) \div 10$$
$$= 23.5625 \div 10 = 2.35.$$

And for outer and middle rows

$3\text{-}10P+d$
$=.3\times 6.68875+.875$
$=2.00625+.875$
$=2.881.$

Of course these dimensions are all the minimum allowable, and if we exceed them it will not matter.

For the thickness of the metal forming the straps we have

$$\frac{5\times T\times (P-d)}{8\times (P-2d)} = \text{Thickness.}$$

Then

$$\frac{5\times 7(6\ 11\text{-}16 - \frac{7}{8})}{8\times 16(6\ 11\text{-}16 - 7\text{-}4)}$$

$$\frac{5\times 7\times 93\times 16}{8\times 16\times 16\times 79}$$

$=.321$ inches.

This is practically 5-16, but it would be just as well to use ⅜ plate, and thus have a margin over size to allow for wasting, and to make a better caulking edge.

The dimensions for the joint will therefore be:

Pitch outside row, 6 11-16 inches.

Pitch inner rows, 3 11-32 inches.

Diameter of rivets, ⅞ inch.

Thickness of straps, ⅜ inch.

Minimum distance between outer and middle rows, 2.33 inches.

Minimum distance between inner and middle rows, 1.66 inches.

Minimum diagonal pitch between inner and middle rows, 2.35 inches.

Minimum diagonal pitch between outer and middle rows, 2.88 inches.

The width of straps will be the sum of the distance between the three rows of rivets, plus 3 diameters, multiplied by 2.

The accompanying dimensioned sketch shows all the particulars.

WORLD-WIDE COAL SHORTAGE A MENACE TO INDUSTRY

As a result of the coal shortage which menaces the world, only the United States and Great Britain are assured of sufficient fuel to operate their industries at capacity during the coming winter, according to Joseph A. Broderick, vice-president of the National Bank of Commerce in New York. In an article on the International coal trade in the October issue of Commerce Monthly, the bank's magazine, he points out that although eventually a balance will be reached between demand and production, this cannot be hoped for in the near future. Neither shipments from new and remote fields nor the increased use of fuel oil and other substitutes will solve the problem for the present.

The article indicates that at the present rate of monthly receipts not a single importing country in Europe or South America is receiving a supply which is even approximately adequate. France is now receiving coal at about two-thirds the rate which would be necessary to assure operation of French industries at capacity; Italian receipts are about three-fifths of the estimated necessary amount; Netherlands is receiving only one-third the amount of coal required by its industries, and Norway is receiving approximately one-half. The situation is no better in the case of the other chief European and South American buyers in the international market.

"Only two countries of the world, the United States and the United Kingdom, to-day have reasonable assurance of sufficient coal to operate their industries at capacity during the coming winter," Mr. Broderick says. "In order to attain this security a definite limit has been placed upon the amount of British coal available for export, and in the United States exports have been automatically held in check by measures taken to assure domestic supplies. The fuel problem is the foremost question facing the industry of every country of Western Europe, except the United Kingdom. It is also to the fore in a number of countries outside Europe, chiefly those countries of South America which have heretofore been dependent on imported coal.

"The international coal trade is entirely dominated by the United Kingdom, Germany and the United States. Not only is the coal supply of importing countries now dependent upon the mines of these three countries, but there is no prospect for years to come of important additions from other sources to the amount of coal available for the export market. The recent emphasis placed upon small shipments from new and remote coal fields has been entirely out of proportion to their relation to the issue. A similar over-emphasis has also been placed on the proposed use of substitutes. Regardless of what the more remote future may hold, the present fuel problem will not be solved by the substitution of fuel oil for coal. The production of electricity from water-power necessitates elaborate installations at a time when capital is costly and difficult to secure, and extensive water-power projects require years for completion. Wood and peat are but poor substitutes for coal, and for many uses lignite likewise is highly unsatisfactory. Modern industry has been built on coal, and it is dependent on adequate supplies for its maintenance.

"The total shortage of coal in the international market is only a small part of the difference between actual production and probable output had the war not occurred, but when measured in terms of the effect on the countries which are suffering this shortage it is acute, and the only hope of meeting it lies in the productive capacity of the United Kingdom, the United States and Germany.

"No comment can add emphasis to the facts. British exports for the year cannot exceed 25,000,000 tons with an additional 13,500,000 tons for bunkerage of vessels in foreign trade. Exports from the United States much in excess of exports for previous years, that is, gross exports of 25,000,000 tons, and 7,000,000 tons for bunkerage, might result in a corresponding shortage for American consumers. Required German coal deliveries are probably in excess of the surplus which Germany would have available for export if German industry were to operate without a handicap.

"The degree to which industry and the routine of ordinary daily life are disorganized in these countries is determined in part by the seriousness of their coal shortage and in part by the extent to which they are industrialized. The north European countries are the worst sufferers. Ultimately a balance will be attained between consumption and production, but it does not appear that this can be hoped for in the immediate future. The international coal shortage is one of the most serious results of the wastefulness of war."

BRANTFORD NEEDS MORE POWER NOW

The shortage of coal, the scarcity of wood in the civic yards there were augmented when the Brantford city council was informed by the local Hydro-Electric Commission that this city was now carrying a load of 200 more horse-power than it was getting, and that the situation would get worse instead of better with the approach of winter, with lessened supply and greater demand. The only ray of hope was shed when the Gas Committee reported that with new fields opening up and available because of increased prices, the Dominion Natural Gas Company would be in a position to give assurance that a greater supply of better quality gas would be available for Brantford this winter.

Although no deposits of anthracite or bituminous coal have been found in Ontario, the province has considerable beds of lignite. This substance is more fibrous than common coal, and though it can be used as fuel, its heating power is much inferior. It also has an exceptional amount of soot and ashes. What we have been needing is some cheap method of converting it into marketable fuel. According to report this method has been found and a plant erected in the State of Victoria, Australia. It was designed and built by Roy N. Buell, of San Francisco. The means employed reduces the moisture in the lignite from 25 to 40 per cent., and an apparatus is used to draw the soot and dirt out by suction. Under test the boiler efficiency of the fuel was 80 per cent. and the furnace 78 per cent. If the process operates successfully, as claimed, the new invention will mean much to the manufacturers of the United States and Ontario.

Oil Firing Installations for Land Boilers

The Following Points on Burning Oil Under Land Boilers Are Reprinted from "The Practical Engineer" and Contain Many Valuable Hints and Suggestions.

By G. F. WARD

WITHIN the last six months much has been said regarding the introduction of liquid fuel for marine purposes. A great number of papers have been written and in some cases they have touched on the application of oil firing for land boilers.

To apply successfully oil firing to, say, a Lancashire boiler, is very different from the application to a large marine water-tube boiler. I do not wish to infer that the same plant would not be successful in working in each case. Such a statement would be erroneous. My point is simply a question of initial cost together with efficiency obtained.

It is, perhaps, more a question of the type of installation to be used: the oil pressure jet system as used for marine work against the cheaper air and steam jet systems.

There is still a great deal of prejudice against the use of liquid fuel for land boilers, chiefly on account of present-day market price of oil. In a great many cases high-grade oil is chosen for comparison. The writer has successfully burnt mixtures of pitch and creosote and the by-product from Mond gas plant, which before the war was worse than useless refuse.

Steam and Air Jet Burners

To deal efficiently with the heavy types of liquid fuel, the steam and air jet systems are much to be commended, more especially for low-pressure boiler plants.

With the steam jet burner, the oil is atomized by the steam pressure and at the same time inducing a quantity of air into the burner, spraying the mixture into the furnace at a high temperature. With this system, between 3 and 4 per cent. of the total steam raised is required for jetting and recovering about 70 per cent. of the calorific value of fuel used.

In large installations the use of air at about 4 lb. pressure is much more economical, and test results have shown that nearly 76 per cent. of calorific value of fuel is recovered in actual work. The additional plant required for air jetting is a small air compressor. Heated air is supplied by leading air pipe alongside flues of boiler, and in the case of the Scotch boiler through smoke-box at boiler front.

Installation

The writer has often noticed that sufficient care is not exercised in the installation, more especially with regard to pipe lines and position of tanks. Main storage tanks should not be less than 40 feet from boiler-house, and, if possible, fixed below the ground level. The advantage of this arrangement is that the supply oil may be quickly discharged into a tank from barrel or railway tankers, and in the latter case does not necessitate keeping expensive rolling stock idle while the oil is being pumped out—often a long and tedious operation.

Suitable heating coils are arranged in storage tanks to assure easy passage of oil to pump, and then to gravity tank. A good plan is to entrench the steam pipe to the heating coil alongside the main oil discharge to pump, thereby ensuring oil being kept at an even temperature from tank to boiler-house.

A small oil pump is required to raise the oil from storage tank to gravity tank. Oil tanks are frequently placed immediately above the boilers, a practice not to be commended on account of danger of the oil dripping upon hot surfaces. A head of about six feet should be allowed from gravity tank to burners.

The question of filtering the oil is often troublesome, owing to oil filter of inadequate capacity being used. The writer has found a large box filter made of iron gauze well fitted in a wire cage to be the most suitable. This is fixed in the gravity tank, the oil supply being let into it and filtering through the gauze into the tank. It is essential that the filter should be kept clean, especially when using very heavy oil. Irregularity in oil supply at the burner is often due to filter trouble.

For both steam and air jet burners, the temperature of oil should be between 135 degrees and 150 degrees Fahrenheit, depending on the density of the fuel. This is best regulated by means of a thermometer placed in a pocket containing water and suspended in the oil gravity tank, the steam supply to the heating coil being adjusted to suit the required temperature. On no account should the oil exceed the temperature of 150 degrees Fahrenheit.

Heating coil joints are better brazed or welded together to eliminate water leaking and mixing with oil fuel. Any accumulation of water in the gravity tank should be drawn off by means of drain cock on bottom of tank.

The best position for the oil delivery pipe connection to burners is about six inches from the bottom of gravity oil tank so as to allow ample room for any sediment to gather which may have escaped oil filter. Whenever possible, straight lengths of oil piping are to be preferred, and should be of ample diameter to allow a free flow of oil and easy cleaning of pipes.

The usual form of furnace front equipment for both steam and air jet systems consists of a large cone-shaped fitting attached to the furnace, the fire-bars being removed. Suitable air ports are cut in the sides of this fitting for the admission of extra air, and the burners are fitted immediately in front of the furnace.

Care must be taken in adjusting extra inlet ports. Admission of an insufficient quantity of air will produce a blood-red smoky fire. The correct flame should be transparent and of an intense white color, or approaching a pink when using light oils.

The writer has seen burners fitted to Lancashire and Scotch boilers with little or no alteration to the boiler fronts giving excellent results. Expensive and complicated boiler front fitting will often give trouble unless a really reliable boiler attendant is in charge.

It is sometimes advisable to line the furnace with fire-bricks a few feet from the front to avoid the oil spray coming in contact with cold plates before complete combustion takes place. A good back bridge of fire-brick is essential, so that the flame will beat against it, and thus avoid striking cold surfaces.

Variations in the boiler load should be met by variations in oil jetting and air control. It is often thought quite unnecessary to regulate the boiler damper when firing the oil. To many there are only two positions for the damper—full open or closed. The attendant acts upon the theory that draught is made to be used, and as much as possible should be used. A little care in this direction will do much in maintaining combustion efficiency.

Burning Solid and Liquid Fuel Together

We are told that large quantities of low-grade fuel are daily placed on the dump heap as being useless. Indeed, it is said that nearly fifty million tons per annum of low-grade fuel is wasted. At the pit head this is termed unsaleable fuel, and is made up of mine sweepings, residues from colliery washeries and such like. Many attempts have been made to burn this fuel in boiler furnaces, but difficulty is always experienced in maintaining the full boiler load, owing to the low value of the fuel.

By the introduction of, say, 15 per cent. of liquid fuel to burn in conjunction with the solid fuel, a great saving in the weekly fuel bill will be effected.

In the case of a Lancashire boiler, a small burner may be inserted immediately over the fire-door at an angle, pointing slightly towards the fire-bars. The oil will then burn immediately over the solid

fuel and will materially assist in obtaining complete combustion.

A similar arrangement may be applied to water-tube boilers, and in the case of generating stations will be found useful in order to enable a sudden demand for extra power to be met. The question of oil firing for land boilers is to be considered in spite of the present high cost of liquid fuel. It has many advantages over coal firing, and, providing care is taken in the work of installation and proper adjustment, little or no trouble will be experienced in operation.

The Construction of a Bell Ringing Transformer

By ROBERT G. FLAVIUS

Copyright. All Rights Reserved.

BY following the instructions herein given, a transformer suitable for a primary voltage of 110 and a secondary voltage of 10 volts can be constructed. The secondary circuit has a capacity of about 1 to 1½ amperes. This device can be applied for any of the services for which bell ringing transformers are ordinarily used. It will ring vigorously an ordinary vibrating signal bell or will light a 10-volt tungsten lamp requiring about half an ampere and producing four candle power. It can also be used for driving such small electrical toys and motors as will operate on alternating current. The secondary winding is provided with a 50 per cent. tap, so that a pressure of five volts can be obtained therefrom.

It will be found that if the transformer is constructed in accordance with the directions its exciting current will be negligible, that is, when it is connected to a source of 110 volts and no current is being drawn from its secondary, practically no current will flow through the primary winding. Such a transformer will not take enough current to operate a watt-hour meter when the secondary of the transformer is open.

Fig. 1 shows the transformer assembled in its case complete. One of the stampings from which the core is built up is shown in Fig. 2. The core mounted on its supporting studs with the winding in position is diagrammed in Fig. 3. Fig. 4 shows the temporary core form upon which the winding is served and in Fig. 5 is illustrated the winding complete. Fig. 6 details the sheet iron case, and Fig. 7 illustrates other details of the device.

In making the instrument, the first move is to cut the sheet iron pieces which will comprise the core. One of these pieces is shown in Fig. 2. The sheet iron from which these core pieces are cut should be as thin and as soft as possible. Any soft sheet iron thinner than 1-32 in. either tinned or plain, will do. However, probably the most desirable material is No. 27-gauge sheet steel, which is about 0.017 in. thick. In any event, enough pieces like that of Fig. 2 should be cut to make a pile of ¾ in. thick. If No. 27 gauge steel is used, about 45 pieces will be necessary. These 45 pieces can be cut from a sheet 18 in. square.

The pieces can be cut with an ordinary tinner's shears. Note that a cut C is made at the upper end of the tongue of each piece. This cut is necessary to provide for the insertion of the pieces in the form wound coil to be described later.

After a sufficient number of pieces have been cut, they are clamped into a pile ¾ in. thick. Then a hole ⅛ in. in diameter should be drilled, in the location shown in Fig. 2, in each of the four corners of the pile. These holes are to accommodate the supporting studs shown in Fig. 3. The supporting studs should not be inserted at this time.

*Copyright, all rights reserved.

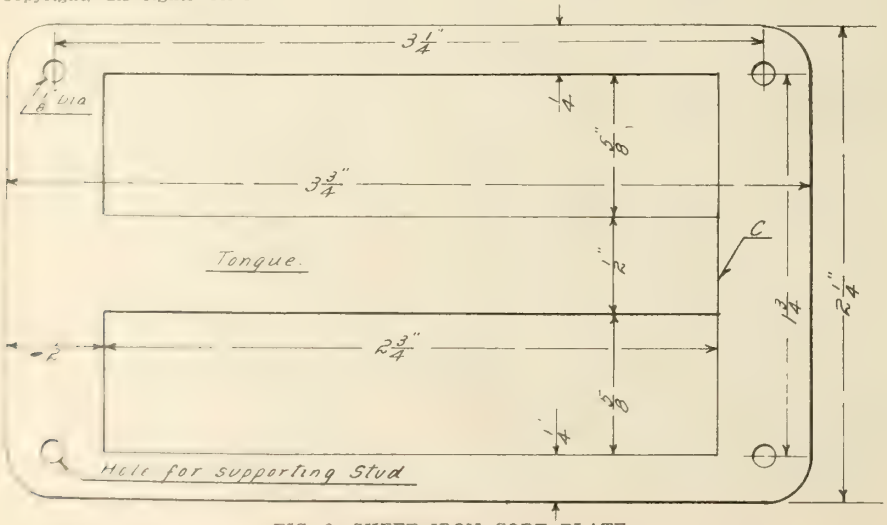


FIG. 2—SHEET IRON CORE PLATE.

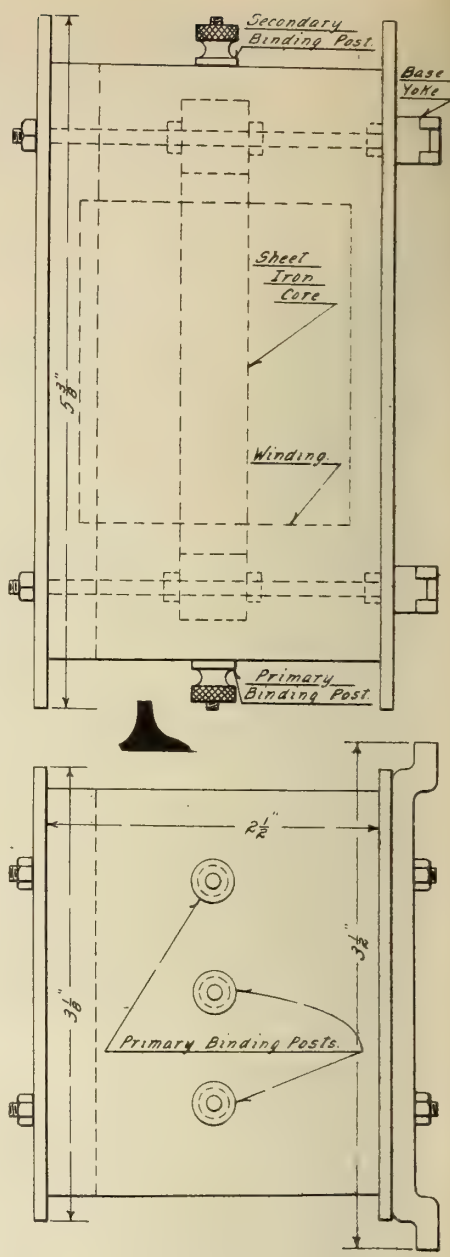

FIG. 1—TRANSFORMER ASSEMBLED.

The next step is to wind the coil. To do this a form is prepared as shown in Fig. 4. This form consists of a prism of wood ½ in. x ¾ in. x 4 in. Its ends should be arranged for centering in a lathe or some other winding device so that it can be rotated. A serving of about a dozen layers of heavy paper is wound around the wood prism, but should not be cemented to the prism. Then a strip of oiled linen or friction tape should be placed at each face of the prism over the paper wrapping. Each of these strips should be about 5 in. long and will project about ½ in. at each end of the block. Now a small wooden block B (Fig. 4), is fastened to each face of the prism with wood screws. These blocks should be so located that there is a clear space lengthwise of 2½ in. between them. In this space, between the blocks, a couple of layers of shellacked paper and four layers of oiled muslin or friction tape should be wound for insulation. The form is now ready to have the windings put on it.

The primary winding should now be served around the form. This should consist of about 3,000 turns of No. 34 wire. Enamelled copper wire should be used if it is available, but if not, double cotton-covered wire can be used instead.

Since the insulation on the cotton-covered wire is thicker than the enamelled insulation, the transformer will be bulkier if it is used. Between every four or five layers of the wire, which should be served on evenly and regularly, a sheet of oiled linen should be inserted for insulation. After all of the turns of the primary winding are in place five layers of oiled muslin should be wound around it and cemented in place with shellac.

Now the secondary winding can be made. This is wound directly over the primary and should consist of about 290 turns of No. 24 enamel-covered copper wire. The same condition obtains with the secondary as with the primary winding, that is, if enamel-covered wire is not available, double cotton-covered wire can be used, but it will require more space for the same number of turns. After half of the secondary winding is in place, a tap about six in. long should be looped out from it to constitute the five-volt tap referred to in the first paragraph.

The winding being completed, it should be tested for grounds between the primary and the secondary and within the primary and secondary. If faults are discovered it will be necessary to rewind the coil to eliminate them. If the windings test clear, the blocks B (Fig. 4), are removed and the ends of the cloth strips S are pulled back to the winding and turned over it tightly. Then the whole winding is served with a couple of layers of friction tape to hold the layers and the ends of the cloth strips in place. This friction tape serving also constitutes a protection for the winding. Now drive the wood prism P, upon which the windings were served, out of the coils. This can be done by tapping on it gently with a hammer.

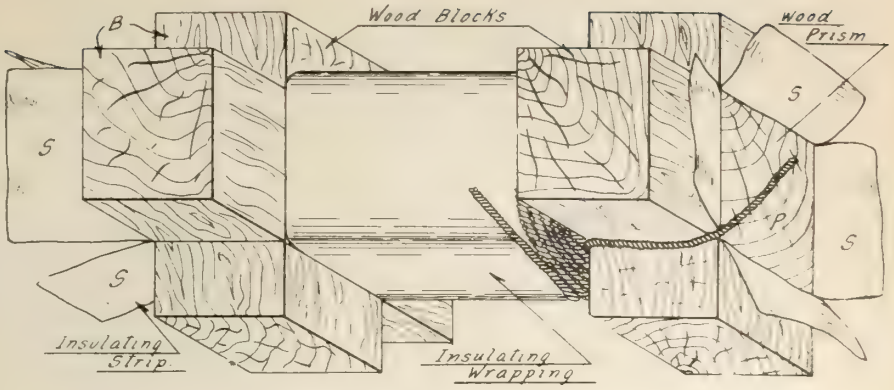

FIG. 4—FORM BLOCK PREPARED FOR WINDING.

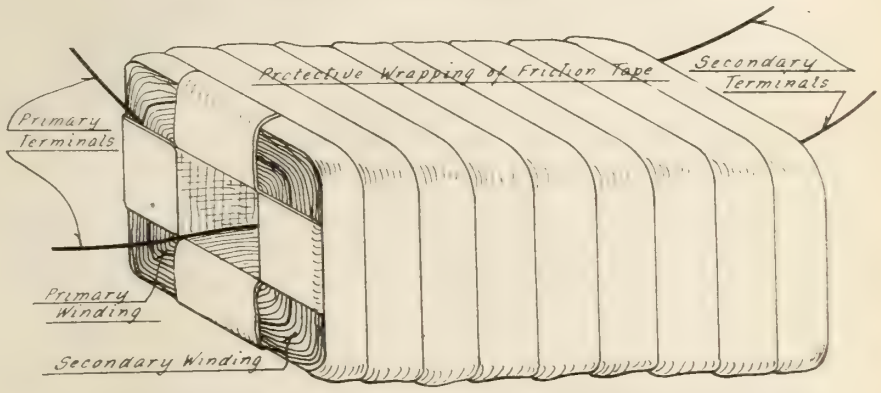

FIG. 5—WINDING COMPLETE.

The coil is now finished and will appear about as shown in Fig. 5. It should be painted a couple of coats of shellac to cement the tape in place and to provide additional insulation.

The core pieces, Fig. 2, can now be assembled in the coil. This is effected by bending the tongue of each strip until it stands at right angles to the balance of the strip. The tongue is then inserted into the hole in the coil and the remainder of the strip bent down until it lies in the same plane as the tongue. This process is repeated with each of the core pieces. In inserting the core pieces, the cuts C, should be staggered, that is, if the first piece is inserted from the right hand end of the coil, the next piece should be inserted from the left hand end, and so on until the pile is built up to the required thickness of ¾ in.

The supporting studs shown in Fig. 3 are made by threading four ⅛ in. x 3 in. round rods. Two nuts are run on each rod after it has been pushed through the core, and then these nuts are set up tightly, binding the core plates firmly in position. Sheet iron, either galvanized or painted, is used for making the case which is detailed in Fig. 6. Three binding posts are set in one end of the case, as shown in Fig. 7-II, for the secondary terminals, and two binding posts for the primary ter-

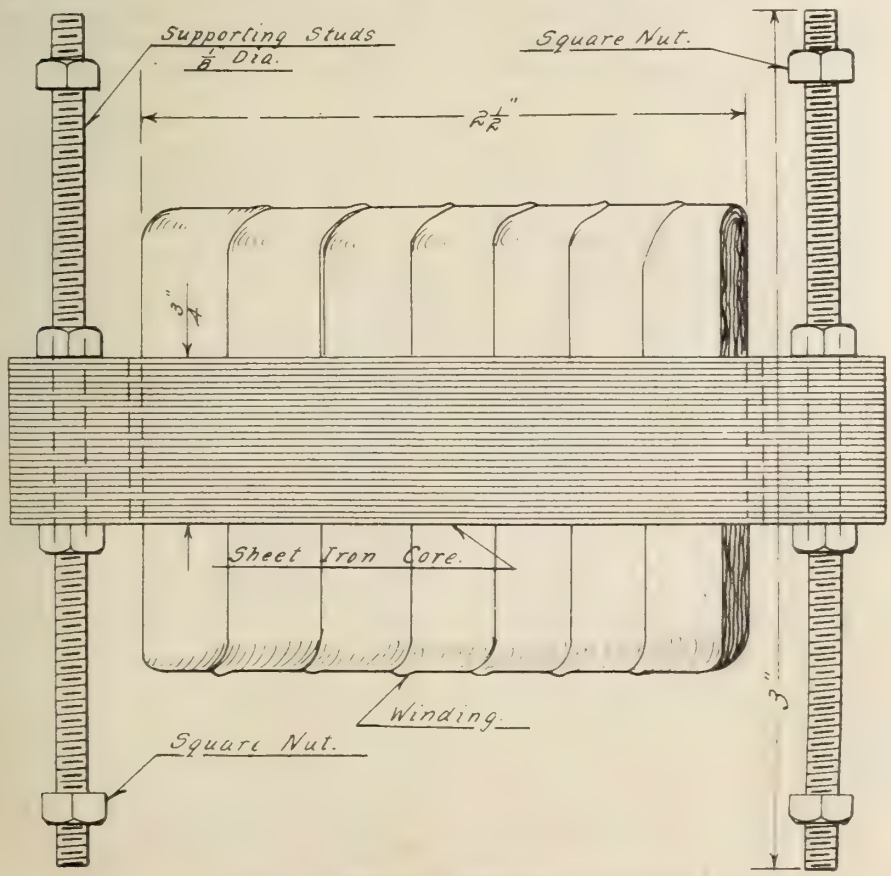

FIG. 3—WINDING ASSEMBLED ON CORE.

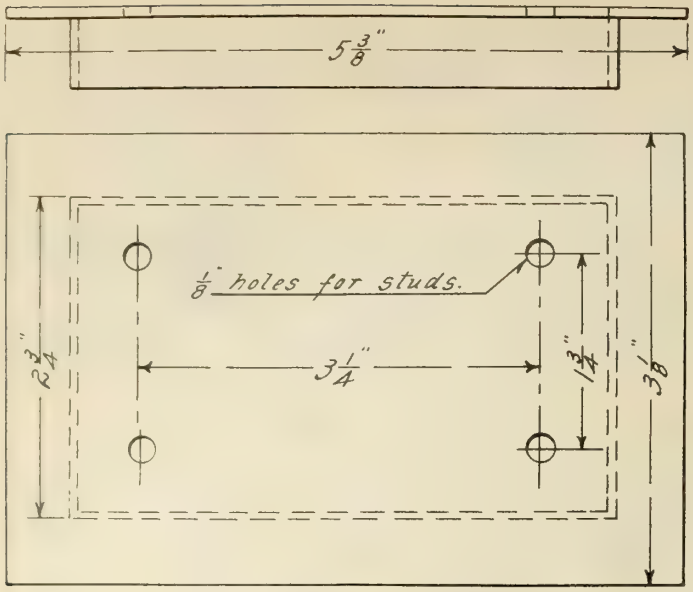

FIG. 6—DETAILS OF COVER.

minals are arranged on the other end of the case. The punchings for these binding posts should be made in the sheet for the case before it is bent into its final contour. The cover for the case shown in Fig. 6 is also of sheet iron. To provide support for the transformer and case, two yokes are bent from strap iron as shown in Fig. 7-I. The two holes in each of these yokes, 1¾ in. apart, are for the accommodation of the supporting studs which are clamped therein with a couple of nuts. The remainder of the construction of the device will be apparent from the illustrations. The two wires from the primary winding should be connected to the primary binding posts. The outside ends of the secondary winding should be connected to the two outside secondary binding posts, and the five-colt tap should be connected to the middle binding post.

These binding posts must be carefully insulated from the case with fibre or mica washers as shown. The stud of each binding post is wrapped with tape where it passes through the metal, which constitutes an insulating bushing.

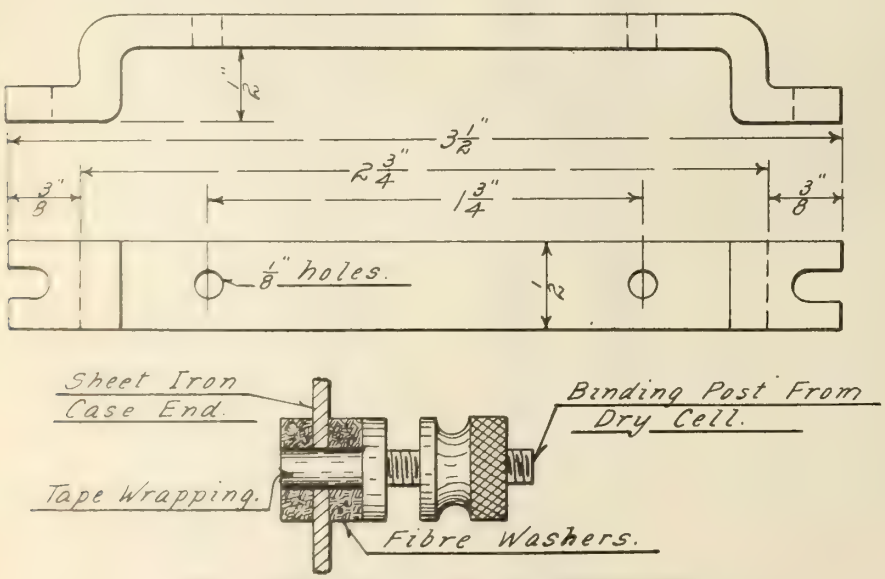

FIG. 7—DETAILS OF YOKE AND BINDING POSTS.

HYDRAULIC NEVER TO REPLACE COAL

Interesting Figures Brought Out by Authority in United States Field

Dr. Charles P. Steinmetz, chief consulting engineer of the General Electric Company, New York, warns against a too general belief that the power of our water may ever completely replace the use of coal and oil for power purposes.

The maximum possible hydraulic energy of the nation, he estimates at the tremendous figure of 370,000,000 horsepower, which is little more than the total energy which we now produce from coal, and is about equal to the present total energy consumption of the country, including all forms of energy.

"This is rather startling," said Dr. Steinmetz. "It means that the idea that when coal once begins to fail we may use the water power of the country as the source of energy, is, and must, remain a dream, because if all our potential waterpowers were developed and every raindrop used, it would not supply our present energy demand.

"Thus hydraulic power may and should supplement that of coal, but can never entirely replace it as a source of energy. This probably is the strongest argument for efforts to increase the efficiency of our methods of burning coal.

"Obviously, of course, we can never hope to develop more than a part of the maximum potential energy of the water, and I merely cite these figures to show that our water power resources, if developed, to theoretical perfection, would still fall short of meeting the energy demands of the country to-day."

The total present developed water power in the United States exceeds 7,000,000 horsepower with 19,000,000 still undeveloped, and potential water power capable of development amounting to 31,000,000 horsepower.

The present use of water power saves the country from upward of 33,000,000 tons of coal annually.

TRADE ANNOUNCEMENT

Announcement is made by the American Steam Conveyor Corporation of a change in their corporate name to the "Conveyors Corporation of America."

The change in name is due to the rapid growth of the corporation, the addition of new lines of business and the purchase at South Bend, Indiana, of a large and completely equipped machine shop to which foundry facilities will be added.

The new name more nearly describes the present business of the organization. Their line includes steam jet conveyors for handling ashes, soot, combustion ash, etc.; trolley carriers for handling coal, limestone, sand, gravel, and like loose, bulky materials; ash pit doors; flood oil bearing sheaves and other conveyor supplies.

The acquisition of a new machine shop at South Bend, Indiana, will afford unusual prompt service and will meet the strictest requirements of the customers.

There is no change either in the personnel or policy of the company.

PORTABLE PROJECTOR

The Graphoscope Development Co., 50 E. 42nd St., New York City, have issued a moving picture apparatus especially designed for the use of salesmen. This complete unit, ready for operation, is packed in a case of about the same size as an ordinary suitcase. It is equipped with a motor drive and is of simple construction. The machine uses standard films and will project a picture 10 feet square at a distance of 35 feet.

EXPLOSION OF A SCOTCH MARINE BOILER

From "Travellers Standard"

Boilers of the Scotch marine type are widely employed in Great Britain, where they are considered to be reasonably safe and economical. They have never been extensively used in American land practice, although they are by no means unknown in this country, and in some sections they are frequently met with. Occasionally one of them fails, and the accompanying illustrations show some of the damage that resulted when an accident of this kind occurred recently. The fireman, who was the only person about the boiler house at the time, was killed, and the property loss amounted to about $7,000.

THE RUPTURED FURNACE.

The boiler that exploded was No. 2 of a battery of two boilers of similar type and size, which were installed in the plant of the Detroit Creamery Co., at Owosso, Mich. Each boiler was 90 inches in diameter and 13 feet 3 inches long. Each had a single furnace, 47 inch in diameter and 12 feet 10 inches long, composed of five sections of steel plate, each ⅜ of an inch thick and about 30 inches long. The furnaces were of the plain type—that is they had no corrugations or stiffening rings or flanges—and the girth and longitudinal seams in the furnaces were of the single-riveted lap-joint type.

The explosion occurred at about 5.30 p.m. on June 17. The furnace of the boiler failed by collapsing throughout its entire length, and by rupturing the first girth seam. About half of the rivets sheared, and the metal in the plates pulled away from the rivets in the remaining part. The rupture extended about 39 inches around the top of the seam, and the upper part of the front course of the furnace was pushed down and forward.

WHERE THE BOILER LANDED.

The fireman was blown across the river and against the wall of an old packing plant—a distance of 500 feet or more. The boiler was thrown some 600 feet in the opposite direction, and struck the rear end of a residence. It moved the house at least a foot on its foundation, crushed a woodshed, and damaged two other houses and a nearby automobile. The boiler house was destroyed, and boiler No. 1 was moved out of position. The steel stacks on the boilers were tipped over upon the creamery building. The boiler shell was not materially injured, and can be put in service again after new tubes and a new furnace have been installed. Examination of the boilers after the accident led the investigators to believe that low water was the primary cause of the explosion. The metal showed evidence of overheating, and there was also testimony to the effect that water was being introduced into the boiler at the time of the accident. The mode of failure also tends to confirm the low-water theory, because the first girth seam, which was in the hottest part of the furnace, would be first affected.

The boilers were constructed and installed in 1913, and at that time plain furnaces were quite commonly used. This construction is not favored at present, however, and would not be accepted for the pressure under which these boilers were operated (namely, 85 pounds) in localities where the A. S. M. E. code, or some other similar code, is in effect. In fact, the A. S. M. E. code limits the diameter of an unstayed furnace of this kind to 38 inches.

NEW BULLETIN

The Hays automatic CO_2 and draft recorder is described in a new bulletin just issued by the Jos. W. Hays Corporation, Michigan City, Indiana. The bulletin describes fully the unpacking, erecting, pipe layout, and operation of the recorder. It is well illustrated, and a diagram of spare parts, numbered to correspond to a spare part index, is included. This is a very useful little book for all users or prospective users of these instruments.

George W. Cole, Ltd., Toronto, have issued a new bulletin descriptive of their steam traps and steam trap installations. Diagrams and illustrations of actual installations are given, and line drawings of the operating features of the trap included. The bulletin also illustrates heaters, check valves, radiator valves, etc., handled by the firm.

CATALOGUE

The Armstrong Cork and Insulation Co., Pittsburgh, have issued catalogues descriptive of their Cork Tile for flooring purposes, also their Linotile floors These catalogues are well illustrated in colors, and the different applications of the flooring specified.

Dominion Motor Castings, Ltd. Incorporators: Clifford Albert Ripley, manufacturer; and others, all of Detroit. Capital $250,000. Head office, Windsor.

Selecting Coal by the Microscope

AT the recent meeting of the Iron and Steel Institute in England, a paper was read by Mr. A. L. Booth of Manchester, in which he drew attention to a method of selecting coal, which is of great interest. After pointing out that though many methods of ensuring fuel economy in the burning of the fuel had been advocated and tried, but little attention had been paid to the selection of the right class of coal for the service required. While a good deal of dependence was placed on analysis where it is used, Mr. Booth claims that this is a very unsatisfactory means of determining the value of a coal. He points out that two kinds of coal may give the same analysis and look practically the same, and yet give totally different results when used in the furnace. Most men who have had much experience in the burning of fuel under boilers will agree with this statement. The conditions under which the test is made in the laboratory, and those under which the coal is burned in the furnace, are so vastly different that there is little wonder that fuels often fail to give the results which might be expected from their chemical classification.

The author of the paper claims that in order to select coal intelligently, it is essential that a knowledge of its formation should be possessed by the person selecting. He is, of course, dealing with British coal seams, and gives the various formations as follows: At the bottom occur leaves, small stems, broken-down wood tissue, etc., from ferns, horse tails and cordiates; and above, the main bulk of the coal is made up of the remains of Lycopods, which include the great Lepidodendrons, Sigilarias, the spore bearing trees, and above these again the "Cannels," which are a class apart. These fossil remains therefore form three types of coals: the "Humic" composed of leaves, stems, and brokendown woody tissues, together with some spores; "spore" coals, in which both "micro" and "Meg" spores predominate, and "Cannel" coals. These coals are not found in absolutely separate and distinct layers, but run into one another, the "Humic" coals often containing a large amount of spores, while the "Spore" coals become more and more "cannelized" as the yellow bodies which are characteristic of cannel merge with the spores. It is due to this condition that the author claims microscopic examination becomes necessary to determine what work a particular sample of coal is most fitted for.

The usual method of classifying coal from the chemical standpoint is by the relation between the carbon and hydrogen, and the relation between carbon and oxygen. These comparisons are, according to the author of the paper, open to objections. He points out that in the "Humic" coals a large amount of cellulose is present, and if this remains even in a small degree in the coal as finally mined and ready to burn, it will have a very marked influence on the hydrogen and oxygen content of the coal. The following tables show this effect. The first table is a chemical analysis of Humic coals, calculated on ash and sulphur free dry coal. These coals swell and coke in the furnace. The second table covers Spore coals, which do not swell or coke, and the third table shows the ratios of C:H and C:O in the two classes of coal.

TABLE NO. 1.

Carbon per cent.	Hydrogen per cent.	Oxygen per cent.
88.0	5.96	5.65
83.2	4.78	11.16
82.6	5.83	10.5
87.6	5.12	5.8
87.0	6.22	5.2

TABLE NO. 2.

Spore Coals

Carbon per cent.	Hydrogen per cent.	Oxygen per cent.
88.0	5.72	5.14

The author of the paper points out that on the strength of these analyses the coals would be classed as bituminous, and in his opinion any system that would class these two kinds of coal together is useless. It was due to the unsatisfactory nature of the chemical classification that the microscopic method has been adopted in England in the selection of 250,000 tons of coal per year.

The microscopical examination showed that there were three main types of coal, each suitable for a particular class of work. Further work showed how far it was possible to go from the particular type without getting a coal that would give unsuitable results. The microscopical examination is used together with a chemical analysis, and the following points are necessary to help in making a decision:

Approximate analysis. 2. The percentage of total sulphur. 3. The percentage of sulphur in the ash. This is necessary to get the amount of sulphur that will be carried

away in the products of combustion. 4. An analysis of the ash itself. This is necessary in order to form some idea of the tendency to form clinker. The author points out further that the laboratory determination of the fusion point of ash is not reliable, as the size of coal, and the the presence or absence of steam influences the point of fusion to a great extent. If powdered coal is to be used, it will be necessary to determine the percentage of phosphorus.

The microscopic examination, it is stated, is useful in determining whether or no it pays to wash coal, and will often explain why a good clean appearing coal will often have a high ash content.

It is also useful in case where there is shortage or a particular class of coal cannot be obtained, in determining the best substitute. The author admits that this method of selecting coal is beyond anyone but the large consumer, but suggests that a number of firms or collieries might combine to perform the work. He holds out the hope that it may some day be possible to buy coal by specification as steel is now bought. He brings out the interesting fact that coal cut from the same seam, at intervals of twelve years, was shown to be of the same type under the microscope. In the published paper are sixteen colored photomicrographs showing the various types of coal, and the text gives their numbers and descriptions of each one. We unfortunately cannot reproduce these photomicrographs.

Although this may seem perhaps to be of only academical interest to many users, it does explain very satisfactorily what has been a cause of wonder to many engineers and coal purchasers. It is quite a usual experience to buy coal which shows a certain heat value by analysis, and find it gives a very much lower value when burned beneath the boiler. This is particularly the case with the very small sizes of anthracite, such as No. 3 and No. 4 bird's-eye, which acts altogether differently in actual practice than in the laboratory. It has a very high ash content by analysis in many cases, but even where the analysis gives a reasonable ash content, the actual amount of ashes pulled from the fire is usually much greater than would be expected. This is due to the low fusion point of the ash, and it has been the cause of many heated arguments and dissatisfaction on the part of plant managers with the man in charge of their plant, and much discouragement to the unfortunate individual who is supposed to get results from it.

The full paper can be obtained from the secretary of the British Iron & Steel Institute, or from the printers, Spottiswoode, Ballantyne & Co., Ltd., Colchester, London and Eton, England.

A Great Natural Resource

THE value of science and scientific research to a country's development was strongly emphasized in a recent speech made by Professor McLennan, of the University of Toronto. It will be well known to many of our readers that Professor McLennan was a very valuable member of the Board of Naval Inventions, presided over by Admiral Fisher during the late war, and it was he who was largely responsible for many of the most successful methods devised to combat the submarine menace, and for the wonderful means of guiding ships through a mine field by means of a submerged cable. In his speech the Professor stated that in the daily press, and in daily conversation, and in daily thought the natural resources of Canada were greatly exaggerated. We had at one time possessed wonderful natural resources, but these had been dissipated and thrown away with a prodigal hand, and we were now faced with the problem of making the best of what was left. Here was the place that science could prove its value. For instance, the great nickel deposits had been denuded of the best of their ore, and the problem was now faced of getting nickel from low grade ore, which was a problem for the scientist. The same thing applied to iron ores. Agriculture was carried on in what seemed to him a most wasteful fashion. Instead of using artificial manures or fertilizers to get an increased yield from the land, a larger area of land was cultivated, which, in these days of high wages and scarcity of labor, added materially to the cost of production. At Niagara Falls was a plant producing cyanide which was a basis for artificial fertilizer, and this was all shipped to the U. S., as there was no sale for it in Canada. The great lignite fields of the Western provinces would soon be available for commercial use, thanks to the achievement of scientific research and experiment. Professor McLennan insisted that the greatest natural resource that Canada possessed was in the intellects of the young men who were growing up now, and he regretted the fact that the most brilliant young men that were turned out at the university were lost to the country. They were taken by firms in the United States who knew the value of scientific research, and opened up possibilities for these young men that were too attractive for them to refuse. Here was another case where our resources were being thrown way. Canada trained these young men and then when they were trained and ready to be of use to their country they were allowed to take their brilliant intellects and capacity for good work away from the country of their birth, which needed them most. This was something for employers and manufacturers in general to think over, and something that is of interest to all Canadians. Prof. McLennan stated that the most brilliant intellects that had come under his notice in recent years were to be found in the large engineering and industrial firms of the United States, who came to Toronto year after year in search of just such material. This is a state of affairs that should never be allowed to continue in a country that prides itself on its wide vision and general business acumen to the extent that Canada does. Professor McLennan's remarks should receive the widest publicity, the more so as they come from a man whose scientific abilities have been devoted to work in the last few years that had a material effect on the ultimate victory of the Allied forces.

Pays Tribute to Business Press

"THAT, in the opinion of this Congress, it is desirable, with a view to the encouragement of closer trade relations within the Empire, special efforts should be made to secure the wider distribution of trade journals throughout the Empire, and that more favorable postal facilities should be accorded by the various governments to the end."

The above is copy of resolution unanimously passed at the meeting of the British Chambers of Commerce held in Toronto. It was moved by Mr. Symonds of the London, England, Chamber of Commerce, and seconded by Sir Thos. Mackenzie, former Prime Minister of New Zealand.

This important resolution stands out in bold contrast with the effort put forward by Mr. E. Nicholls, Director of National Publicity for the Government at Ottawa, to legislate the trade and technical papers out of business. In spite of the opposition of M. E. Nicholls and J. E. Atkinson of Toronto Star, the Chambers of Commerce of the entire British Empire composed of many of the best trained business and technical experts have seen fit to pass this resolution emphasizing the great importance of the specialized business and technical press to those who would better understand conditions in the various parts of the Empire. The incident again shows the need of our governments selecting men of clear-sighted vision to look after the country's welfare.

Progress in New Equipment

PUMPS FOR CORROSIVE LIQUIDS

The development of the chemical industry continually makes demands upon the engineer for apparatus of a special kind, which, furthermore, is required to operate under conditions which call for properties entirely outside the ordinary characteristics of mechanical equipment.

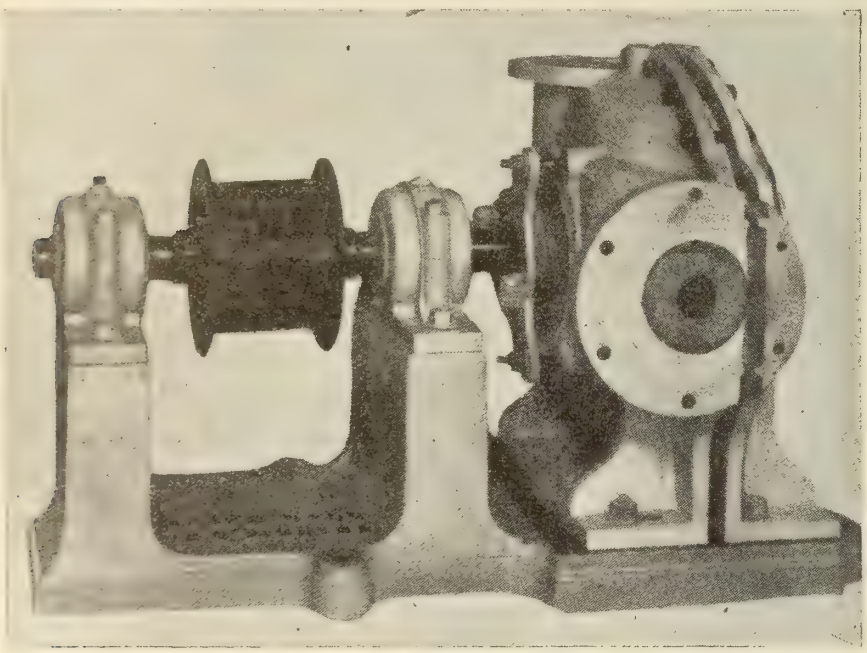

FIG. 4.

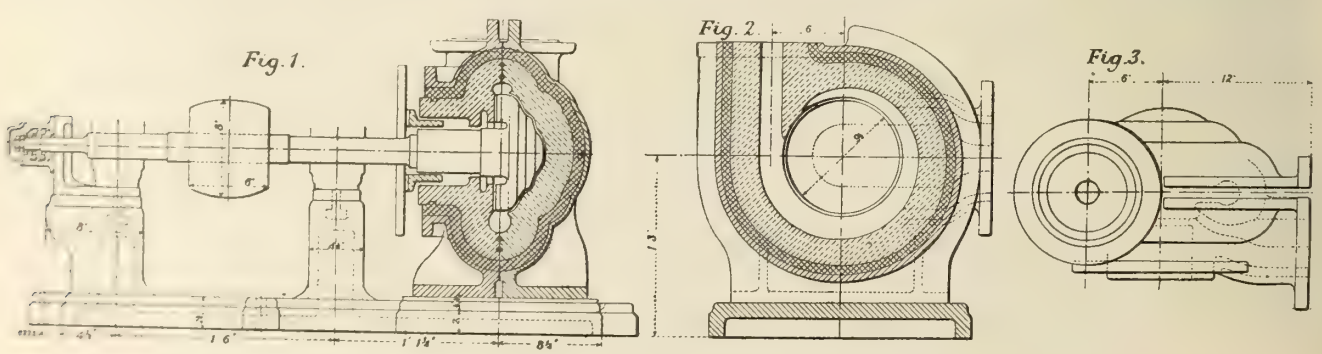
Strongly corrosive liquids have to be pumped and stored, often at a high temperature and considerable pressure, and not only must this be done with complete safety to the operators, but the apparatus must be neither dissolved, corroded or eroded in the process. Should the pumps, piping or vats, etc., be attacked by the substance in contact with them, their rapid destruction might be the least of the trouble. Any such attack would necessarily contaminate the chemicals with the dissolved material, and might easily be serious enough from this point alone to render the process impracticable.

When the conditions are very severe, pumps of the reciprocal type are out of the question, as the centrifugal pump with its natural simplicity of construction, its absence of internal rubbing surfaces and its freedom from valves possesses obvious advantages. Centrifugal pumps, therefore, are widely used for pumping corrosive liquids, and they are made of various materials. Ferro-silicon will resist some acids, but cannot be used for hydrochloric acid or in processes where contamination with iron must be avoided. Lead and regulus metals are also used for pumps but are unsuitable for some acids and for solutions containing metallic salts. Ebonite pumps have been built, but these naturally will not withstand hot liquids, while certain chemicals will attack them. Moreover, ebonite is a bad material for the rubbing surfaces of the glands.

The substance which is most generally suitable for resisting the action of corrosive liquids is some kind of silicious ceramic material, as this can be obtained in forms which are quite insoluble in almost any liquid. Ceramic material is also of a very hard nature, so that it is practically unaffected by erosion. Hence, in spite of its intractable disposition and somewhat unsatisfactory mechanical purposes, it has been brought into use for many purposes. A new acid-ware, called ceratherm, was prepared during the war under the necessity of finding some substance suitable for apparatus for the condensation of large quantities of acid gas. Like silica-ware, it can be plunged when red hot into cold water without cracking, and its good heat conductivity permits of a rapid equalization of temperature in vessels of which it is made.

A modified form of ceratherm, having a higher tensile strength, and possessing the further advantage of being more easily manufactured to accurate dimensions, has been adopted by Messrs. Guthrie & Co., of Accrington, in the manufacture of their acid-proof pumps and other articles. The material is entirely unaffected by almost every chemical solution and may be brought into contact suddenly with either hot or cold liquid without any danger of cracking. The use of this material has enabled Messrs. Guthrie & Co. to put on the market a line of pumps which mark a distinct advance in design and construction over the German made apparatus which was used in this country before the war. The general nature of the ceratherm acid-proof pump will be understood from Figs. 1 to 6. The acid-proof material,

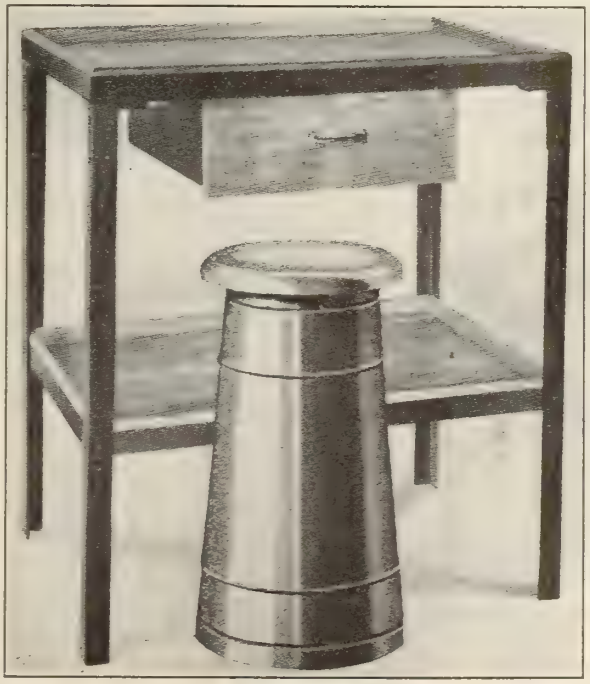


FIGS. 1, 2 AND 3.

FIGS. 5 AND 6.

forming the body of the pump is very thick and strong and is cemented into an iron casing. It is so arranged that it is only subjected by the bolts to crushing stress. The gland through which the spindle passes is usually on the suction side, so that it is relieved from pressure and the stuffing-box is packed with a small quantity of wool, usually soaked in paraffin wax. Various types of impeller are used, according to the duty required. Figs. 5 and 6 show open and closed types in position in the half-casing of the pump. In Fig. 5, the gland is on the pressure side. In all cases the impeller shaft is continued right through the gland and the internal metal spindle is screwed into a cementing material which fills the interior of the shaft and is also held by screw threads formed in the latter. When the impeller is mounted it is ground and balanced on its own spindle. The thrust of the impeller when working is taken up by a ball bearing at the end of the spindle far removed from any danger from acid. The requirements of the chemical industry usually call for a pump designed for lifting comparatively small quantities, say, from 20 gallons to 100 gallons per minute, against a head of anything up to 120 ft. Comparatively high efficiencies are claimed for these little pumps, although when the total power absorbed is so small the question of efficiency would not seem a serious matter. Ceratherm pumps have been built for a head of 300 ft., which corresponds to a pressure of 130 lb. per square inch in the pump casing. Four-inch pumps are constructed to deliver 400 gallons per minute at a head of 90 ft. when running at 1,000 r.p.m. The range of sizes built by Messrs. Guthrie & Co. runs from deliveries from 10 gallons to 5,000 gallons per minute, and comparatively slow rotational speeds are adopted, so that the usual factor of safety of the impellers is about 15 at the normal speed of the pump. They have been used successfully for some years on a commercial scale for pumping sodium peroxide, both hot and cold solutions, a substance which is very troublesome to pump and for which a metallic pump would be useless as the slightest particle of metal passing into the process would do considerable damage. Other awkward liquids such as hydrochloric, nitric and acetic acids, both hot and cold, are also being handled successfully by pumps of this type, and, in fact, the makers claim that they have not yet found any liquid which the ceratherm pump will not deal with successfully.

In addition to the use of ceratherm for the construction of pumps Messrs. Guthrie & Co. employ the same material for valves and for the linings of acid eggs and large vats, etc., as its smooth surface and indestructible qualities make it valuable for many chemical purposes. The firm also specialize in chemical engineering plant of other kinds and manufacture large grinding pans, mixers, hot-drying plates, etc., so that the British chemical industries can now be equipped with the most modern kinds of plant without the necessity of recourse to Continental makers.—"Engineering."



VIEW OF THE STOOL AND THE TOOL STAND.

TOOL STANDS, RACKS AND STOOLS

The old days when a manager would discharge a man for sitting down to his work have passed. It has been proved that for certain classes of work the workman can become more effective by sitting, and the same holds good insomuch that men are no longer allowed to waste time running all over the shop to find tools. Nowadays tool stands, drawers and benches are always handy to the various machines, or at least such is the case in the real up-to-the-minute plants.

The National Engineering Co., Ltd., Sarnia, Canada, are firm believers in all the above statements and to follow out their belief have placed on the market a varied line of time savers. These include tool stands of various nature and sizes, some being supplied with drawers and some without. They also market an all steel storage rack which can be built in any number of sections and combinations for use against a wall, or placed back to back. Such racks are especially useful in warehouses, or in the cut off department.

In addition to the above mentioned lines they make a shop stool of novel design. This stool is depicted in the illustration standing alongside one of the tool stands as made by this concern. The stool is so simple, yet efficient, that it requires no explanation except that it is made in three heights, 24-ins., 27-ins. and 30-ins.

The A. R. Williams Machinery Co., Toronto, are handling this line and will be pleased to give all information regarding the same upon application.

Owing to the Seamen's Union calling out the crews of all Canadian vessels in harbor, to enforce their demands for increase in wages that amount to 25 per cent., seven Canadian ships are tied up in Fort William harbor. There is no indication as to how long the strike will last as the whole walk out is operated from headquarters in Toronto.

COAL OIL LAMPS

The Standard Meter Co., Ltd., 10 Morrow Ave., Toronto, Canada, have placed on the market a very interesting line of lamps which are described herewith. At Fig. 1 is shown what is known as

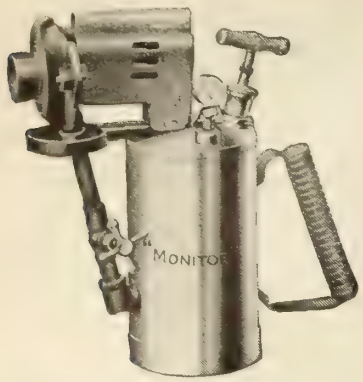


FIG. 1—SHOWING BRAZING LAMP.

the Monitor high power coal oil brazing lamp. This lamp is used for brazing and work of similar nature on a large scale and can be used in any position. It is said to be both portable and powerful. They are made in 2, 4, and 5 pint sizes.

The next type of lamp shown at Fig. 2 is known as the Monitor high power coal oil blow lamp. This style of lamp is both wind and rain proof and is used extensively by millwrights, plumbers, electricians and hot water engineers. This lamp is made in 2-3 pint, 1 pint, and ½ pint sizes.

Another type of lamp carried by this concern is known as the Petropark high power inverted incandescent coal oil lamp. The latter style lamp is used as portable light for country railroad stations, farm buildings, fair grounds,

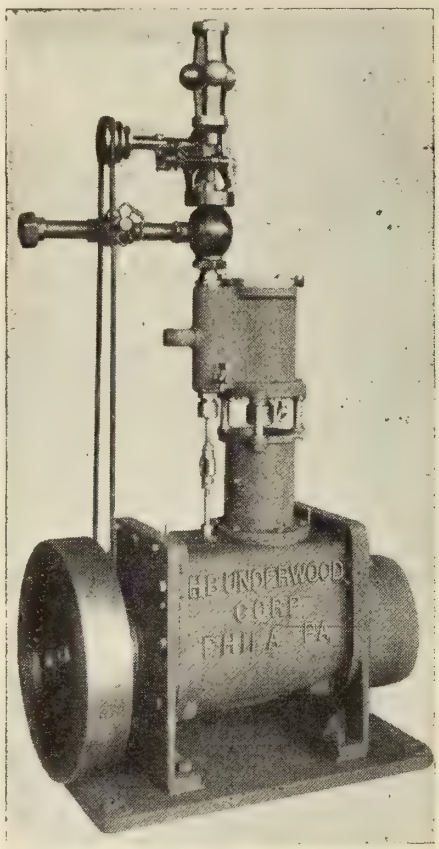
FIG. 2—SHOWING BLOW LAMP.

large workshops, wharves and other innumerable places where portable lights are desired.

AIR OR STEAM ENGINE

The H. B. Underwood & Co., 1015-1025 Hamilton Street, Philadelphia, Pa., have placed on the market what are known as their 3 and 5 h.p. steam or air engines. These engines are built in the two sizes above mentioned, and the illustration herewith gives one a good idea of their general appearance. They are used and designed for driving portable tools such as boring bars, valve seat rotary planers, drilling machines, etc., and are constructed to use either compressed air or steam.

All working parts are enclosed in an oil tight case, which is formed in the base of the engine, making it dust



GENERAL VIEW OF THE ENGINE.

proof, and reducing wear to a minimum. The cylinder of the 3 h.p. engine is 3½-inches diameter and of the 5 h.p., 4½-inches diameter, both engines having 3 1-2-inch stroke. The design of the piston valve used is said to reduce friction and wear to a minimum.

The crankshaft is a solid forging-finished 1½-inches diameter. The engine is well balanced, uses 70 to 125 pound pressure, and runs at 250 r.p.m. This engine should particularly interest railroad shops.

The floor space required is 12-in.x 21-inches, and the height from base to extreme top of governor 46 inches. The net weight is 270 pounds.

Word has been received that Sir Walter Runciman, who recently sold the Moor Line, has formed the Runciman Steam Navigation Co., with a capitalization of one million pounds.

H.P. PER TON REFRIGERATION

Question.—Would you kindly answer through your valuable paper the following: What horsepower will be required per ton of refrigeration with 50 lbs. suction pressure and 185 lbs. head pressure?

Answer.—With the suction pressure at 51 lbs. gauge and the head pressure at 185 lbs. gauge for each ton of refrigeration, 1.8 cubic feet of gas per minute must be pumped. With suction pressure at 15 lbs. and the same condenser pressure about 3.8 cubic feet must be pumped. The mean pressure of the indicator diagram in the first case will be 81.02 lbs. per square inch, and in the second case 68.82 lbs. per square inch. The horsepower required in the first case is .6398 per ton of refrigeration, and for the second case 1.1467.

The following formula for the i.h.p. per ton of refrigerating capacity is by Professor Lucke, of Columbia University, a recognized authority on heat engines:

a = Area of piston in square inches.
p = Mean effective pressure, lbs. per square inch.
L = Length of stroke in feet.
n = Number of compressions per minute.
Ec = Apparent volumetric effieiency. The ratio of the volume of ammonia apparently taken in per stroke to the full displacement of the piston.
Wc = Weight of 1 cubic foot ammonia vapor at the back pressure, as it is in the cylinder at the beginning of compression.
Lc = Latent heat of vaporization available for refrigeration.
288,000 = B.t.u. equivalent to one ton refrigeration.
T = Tons refrigeration per twenty-four hours.

$$\frac{\text{I.H.P.}}{\text{T}} = \frac{\text{plan} \div 33{,}000}{\dfrac{\text{La} \times \text{Ec} \times \text{nWc} \times \text{Lc} \times 60 \times 24}{144 \times 288{,}000}}$$

$$= \frac{.87}{\text{Wc} \times \text{Lc}} \times \frac{\text{p}}{\text{Ec}}$$

The volumetric efficiency varies between 73.5 per cent. and 84 per cent., according to experiments made by Professor Denton.

Refrigerating machines work at their highest efficiency when the range of temperature is a minimum, so that a low head or condenser pressure, with a high suction or evaporator pressure, is the condition to aim at.

A peculiar incident took place when an ocean going vessel for the first time since the completion of the Quebec bridge had to step one of her masts in order to pass under the structure. The vessel was the Grand Duchess Maria Mikoldevna, a full rigged, three masted sailing ship, and the first of its type to visit Montreal for a long period. The vessel belongs to the Russian Volunteer Fleet.

DEVELOPMENT OF LONG DISTANCE TRANSMISSION

(Continued from page 443)

There is one feature of the electrical history of that time which, while disagreeable to contemplate, in retrospect should not be overlooked.

With the entrance of Mr. Westinghouse into the field of electric lighting, beginning in the year 1885, there began a controversy between the alternating current system as championed by Mr. Westinghouse, on the one hand, and the direct current system, as championed particularly by Mr. Edison and his coterie, on the other hand. This controversy became exceedingly bitter. When the alternating current system first appeared the direct current system was the established system and the advocates of the direct current system used every possible means to retard the development of the alternating current system. One of the results, for instance, of this controversy was the decision on the part of the State of New York—unquestionably instigated by some ill-advised advocates of the direct current system—to use electricity for the purpose of executing criminals. Naturally, alternating current was employed for this purpose, and it was brought about that a Westinghouse alternator was secured for this purpose, and the fact that it was Westinghouse was advertised far and wide. Another phase of the controversy was the introduction of a bill in the legislature of the State of New York making it unlawful to use alternating current voltages in the public streets of above a certain specified maximum, which was placed at such a point that the alternating current system could not have continued to exist had the bill passed. Fortunately, the bill did not pass and the alternating current system passed a critical point in its history of development.

The controversy which took place between the systems did no good to either. It unquestionably retarded the development of the electrical art for many years. The advocates of each system sought almost as much the discredit of his competitor's system as he did the advancement of his own. I believe that I am right in saying that most of the gentlemen who were responsible for the initiation and continuance of this controversy lived to see the error of their course and to regret very much that the controversy ever started. They now recognize that the art was retarded by the controversy and that no permanent advantage was gained by either side.

One of the unique phases in the history of the development of power transmission and distribution is that the first installation of a power transmission by alternating current — which was carried out in the year 1890 — was carried out not by means of the polyphase alternating current system, and the induction motor, which we know so well to-day, but by means of a single phase synchronous motor which was operated by a duplicate machine, running as a synchronous generator and driven by the prime mover. This development was carried out in the mountains of Colorado during the year 1890. The voltage of the transmission was 3,000, the distance was approximately three miles and the amount of power was approximately 100 h.p.

As indicated above, the motor and the generator were identical single phase machines, except that the generator was separately excited, whereas the motor was a self-excited machine. While the Tesla motor had been invented about two years previously, it is significant to note that it was not used in this case; however, a Tesla motor was used for the purpose of starting the main single phase synchronous motor. A small Tesla motor was started up as a split phase motor on a single phase circuit, and its pulley was then brought into contact with the main pulley of the synchronous motor, and by this friction drive the synchronous motor was brought up to speed. After being brought up to speed it was synchronized in the usual way and thrown in on the transmission line. The system was then ready to operate. In this day of the universal use of the induction motor it is interesting to look back and see that the first power application of the alternating current system was carried out not by the use of the induction motor, but by the use of the synchronous motor.

It is also interesting to note that the power development for this time later developed into the well known Telluride Power Company. The Telluride Power Company later became a very prominent factor in the development and transmission of power throughout the Central West, covering much of Western Colorado, Central Utah and Southern Idaho. The chief spirit in the promotion of this power company was Mr. L. L. Munn, and he, together with his brother, Mr. P. N. Munn, became the moving spirits in the Telluride Power Company.

The mining industry in Colorado and other Western States was a very profitable industry at that time. Many of the mines, however, required power in considerable quantities in order to make them pay. Before the advent of electric power it was customary to use steam power, generated from fuel which had to be hauled to the immediate vicinity of the mine. In many cases the expense of hauling fuel was prohibitive, and as a consequence rich mines had to be abandoned on account of the fact that the cost of the necessary power was prohibitive.

(To be continued)

TRADE NEWS

The Jeffrey Manufacturing Co., of Columbus, O., have opened a new branch office in Buffalo, at 1108 Marine Trust Building, with Mr. H. W. Scott in charge. Mr. Scott is very conversant with the Jeffrey products, which are well known to engineers, and cover elevating, conveying, pulverizing and portable loading machinery.

Warren Webster & Co., of Camden, N.J., for whom Darling Brothers, Montreal, are the Canadian agents, have issued several bulletins covering their product, contained in a neat binding on the loose leaf principle. The bulletins describe the heating systems, heaters, separators, radiator traps, etc., made by the firm, which can all be procured from Messrs. Darling Bros., Montreal and Toronto.

FOR SALE—ENCLOSED LIQUID FUEL COMbustion apparatus capable of generating intense heat in pipes and confined passages for heating parts of internal combustion engines and for other uses; spark ignited; blower operated. Patented October 8th, 1918. Can be inspected at and for sale by H. W. Petrie, Limited, 131 Toronto St. W., Toronto. (p1h)

Bruce Macbeth Gas Engine 100 H.P. Natural Gas 80 H.P. Producer Gas—Attachments for both—New Clutches—Floor Stands, Shafting and Pulleys, $2,000. Immediate shipment from Central New York.

WANTED—EXPERIENCED BOILER DESIGNer by large manufacturing plant in Ontario. Apply Box 92120, Power House.

NON-CORROSIVE
CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
NOS. 242 TO 244 SOUTH ST. NEW YORK, U.S.A.
FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done—give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

E. H. KELLOGG & CO.,
New York, U.S.A.

FAIRBANKS-MORSE

Helping Canada's Great Railways

The industrial development of Canada is measured by its great railroad systems. Thousands of miles of steel, extending from coast to coast, reaching out from the big manufacturing centres, have been pioneer steps in the country's advancement. And The Canadian Fairbanks-Morse Co., Limited, has been a factor in this development.

Wherever construction gangs have followed surveyors, Fairbanks-Morse railway equipment has been used because of its dependability—dependability that made it worthy of its part in this pioneer work.

From the smallest drill to the electric locomotive—the stand pipes and water tanks that feed the great transcontinental engines—Fairbanks-Morse railway supplies render a service backed by the organization's high efficiency.

The 100% quality seal that marks all Fairbanks-Morse railway equipment is the ideal of the Fairbanks-Morse institution—the mark that symbolizes a standard of equipment and service.

Make this mark your guide in buying.

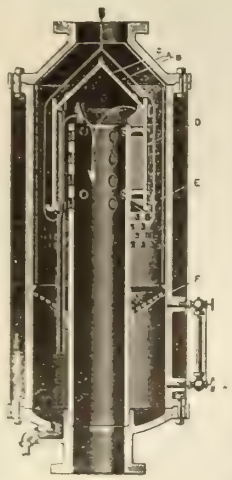
III IMPORTANT THINGS
TO CONSIDER ABOUT
A SEPARATOR



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE — Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION — Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

Sweet's Separators

"The Valve with a Backbone"

Rubber For RESILIENCY
Steel For STRENGTH

A combination that forecasts the perfect valve service. Neither the all-rubber valve with its tendency to dish and blow through under pressure nor the all-metal valve with excessive weight can, efficiently, meet to-day's demands.

Voorhees Rub-Steel Valves

unite the virtues and eliminate the objectionable features of both. By a new process tough, resilient rubber and a strong, rigid steel plate are securely attached, creating a valve that will not warp, buckle, crumble or clog the pipe line.

Made in four grades.

Exclusive Canadian Agents for
Voorhees Rubber Mfg. Co., Jersey City, N.J.

DURABLA
TRADE MARK REGISTERED

STRENGTH—GOODNESS—QUALITY

Performance Facts of Durabla Gasket Material

Tight joints are made and maintained by DURABLA under the following severe services and conditions:

Steam:	275-300 lbs. pressure; 275°-300° superheat.
Oil:	Pressure still joint re-made over 160 times.
Gasoline:	Cylinder heads of gasoline engines and pumps.
Acids:	All acids that can be carried in pipe lines.
Water:	Equally satisfactory with temperature of 40° or 210° F., at any pressure.
Ammonia:	Both absorption and compression systems of refrigeration.
Air:	Air lines and cylinder heads of compressors—all types.

One Standard material for all gasket work—Sold on a Service Basis

DURABLA is sold in sheet or gasket form and the trade mark is stamped all over the material.

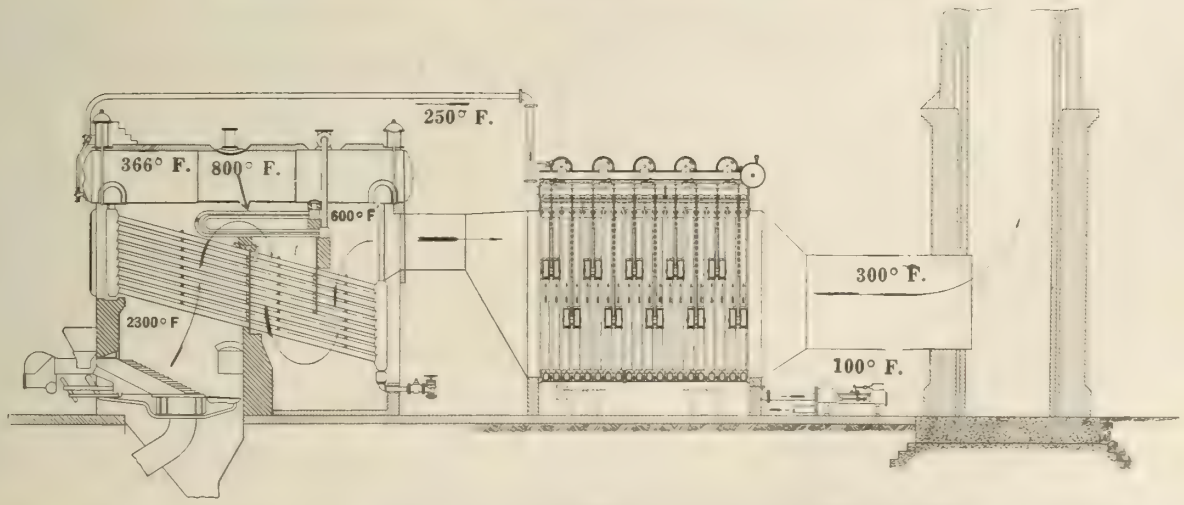
PRATT & CADY PRODUCTS

GREEN'S ECONOMISERS



A Saving of 13.6%

Green's Economiser "installation temperature diagram," showing a rise of 150° in feed water temperature above that of the feed water heated. This is not an unusual case, and under these conditions would show a saving of 13.6% based on 1% saving for each 11° increase in feed water temperature.

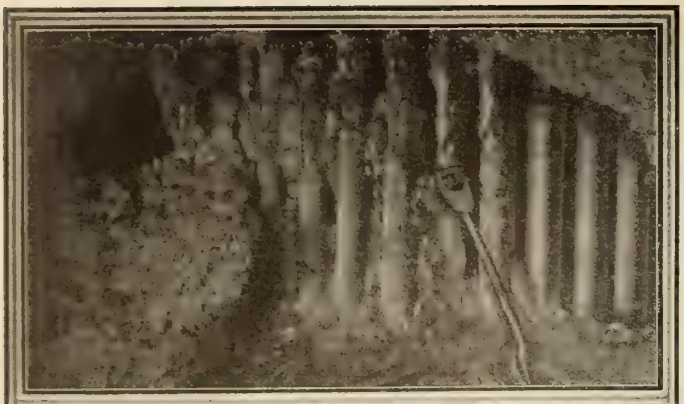
Modern economic operation of boiler plants demands that your boilers be operated above normal rating. This means higher exit temperatures of the flue gases.

Green's Fuel Economisers utilize this heat in the flue gases to heat the feed water under boiler pressure, which accounts for the fuel saving and also allows you greater boiler capacity.

Ask our engineers for data on economisers for your plant.

GREEN'S ECONOMISER, LTD.

TORONTO



Can YOU Afford It?

Soot and ash deposits on the fire surface of boilers cause a loss of millions of dollars annually.

Your proportionate share in this loss depends upon the number of boilers you operate, the cost of coal, and the degree of cleanliness obtaining.

Suppose you have four 500 H.P. boilers. Normally these will require 4 tons of coal per hour, or 20,000 tons of coal per year on a 5,000 hr. basis. At present prices, this coal probably will cost you $100,000 per year.

If you customarily allow your boilers to get in the condition shown in the picture before cleaning them, your loss is anywhere from $10,000 to $20,000 or more per year.

If you clean your boilers regularly and conscientiously with the hand lance, your loss is from $4,000 to $8,000 per year, depending upon the skill of the fireman.

If you clean your boilers with Diamond Soot Blowers you incur no loss, but get value received in steam (within the limitations of your furnaces and boilers) for every dollar spent for coal.

Best of all, Diamond Soot Blowers cost but a fraction of the annual saving.

Ask for Bulletin 280.

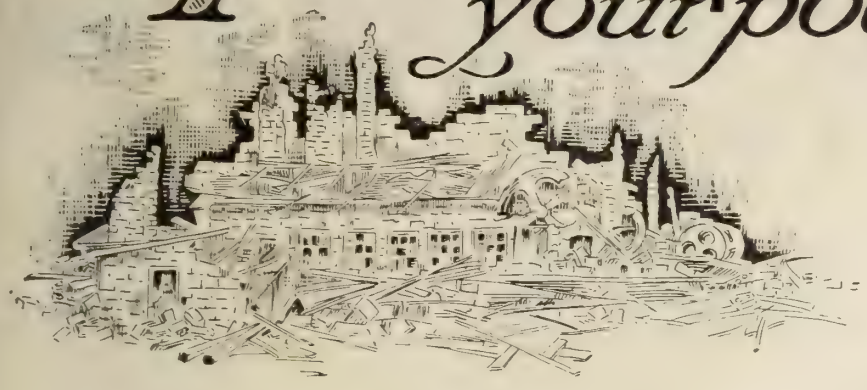
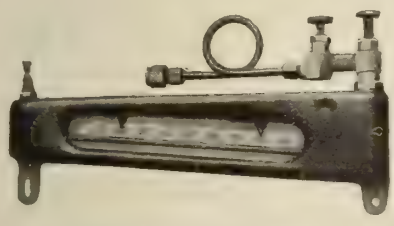
"No Seat to Leak"

If the wind wrecked your power plant

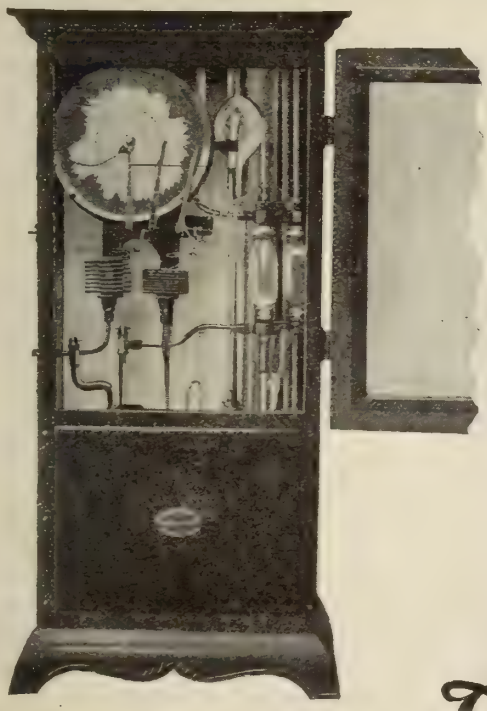


You would know there had been a big loss on account of too much draft. The insurance might partly cover the damage, but you would be able to see the terrible waste and know the reason for it.



HAYS DRAFT GAGE

The everyday losses resulting from too much draft over the fire in your boiler furnace, may go on undiscovered because unseen. Every time the wind changes or the resistance of the fuel bed varies, the draft changes. Excess air taken in, reduces furnace temperatures, burns up your expensive fuel that is so hard to get and causes untold waste that is not covered by ordinary insurance. Accurate knowledge of conditions is the only insurance that will rid you of this large overhead cost.



HAYS AUTOMATIC CO_2 AND DRAFT RECORDER

Awarded Certificate of Merit by the Franklin Institute

Your fireman should have up-to-the-minute information about the draft and the condition of his fires; you should have a daily chart record from the HAYS AUTOMATIC CO_2 AND DRAFT RECORDER to point out the otherwise hidden wastes that swell your fuel bills.

When you consider Hays Apparatus you automatically assign "Hays Service" to cut down the high operating costs of your Power Plant.

Descriptive literature on request. Have you received your copy of the booklet "Fuel"?

The Jos. W. Hays Corporation

Combustion Efficiency Appliances

Michigan City, Indiana

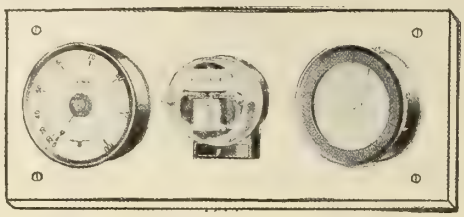
Republic TWINS

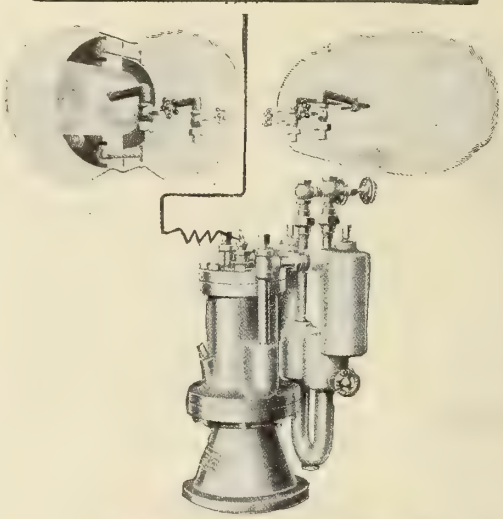
Trading Flow Meters for Boilers

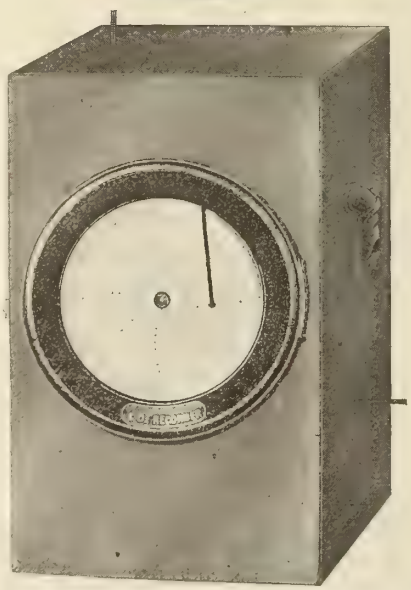
BY installing Republic Flow Meters on a battery of six boilers, a well-known traction company avoided ordering two additional boilers to take care of its peak load. Not only was the cost of the boilers avoided, but also the continual expense of keeping additional boilers banked under light load during the off-peak part of the day. This Company traded Flow Meters for boilers at a tremendous profit.

When you consider that a saving like this is merely incidental to the many economies brought about by tracing erroneous conditions during the regular operation of the boiler room, you begin to realize how really indispensable an installation of Republic Flow Meters IS.

In every-day operation the Republic is a constant guide to furnace efficiency—a continual indication of the performance of individual boilers—an indisputable record of power costs by Departments.







Trading CO_2 Recorders for COAL

COMBUSTION means a combination of carbon with the correct amount of air. If too much air is admitted then coal is wasted. The only method of checking continuously and correctly is by the use of a CO_2 RECORDER. If a CO_2 Recorder is installed, the amount of air cut down, then the amount of coal is lessened; in fact, you have traded CO_2 Recorder for coal.

With coal at the prevailing prices, a CO_2 Recorder is a very good investment under such conditions.

Also by the use of a CO_2 Recorder **Black Smoke is avoided.**

Republic CO_2 Recorders have no valves, no glass (tubing or otherwise), only two moving elements, no complication of mixtures, absolute absorption insured by long travel of gases through absorbent.

WHY DO YOU ADVERTISE

When You Are Behind In Deliveries ?

THIS seems to be a very natural question, and the answer involves the discussion of a vital policy of this business—a policy that is fundamental.

If we were building a business for to-day our policy would vary from day to day with the temporary changes with which every business has to contend.

But we are building for the time to come and we hope that this business will become many times greater than it is to-day. Without the proper foundation it would undergo violent changes dependent upon temporary national, local or even imaginary conditions.

If we should permit ourselves to become inflated with self-confidence when business conditions are favorable, restricting our selling and advertising activities, and go down in the dumps when conditions are not so favorable, this business would not amount to any more than the existing conditions would make of it.

We say right now, without reservations, that we hope, regardless of how aggressive and efficient our manufacturing department may be, that it will never be able to catch up with our selling organization.

If our efforts should be halted in the middle of the road in times of liberal buying to wait on the manufacturing department, there might come a time when the manufacturing department would have to suspend operations while waiting on the sales organization.

With such a policy we would be running around in a circle, disorganizing one day and reorganizing the next.

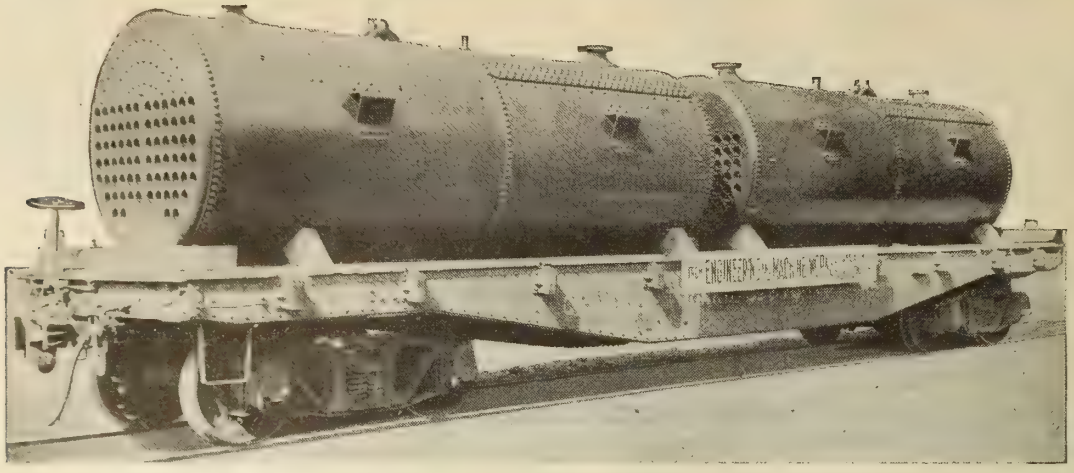
The greater the demand for our product, the quicker the turnover for merchants; and the more frequent the turnovers, the larger is the volume of profit.

In this business advertising is a sales policy—the same as our policy of maintaining a sales organization—and we might as well consider the elimination of one as the other. Neither will be eliminated, as this business needs both if we are building for the future.

We hope the idea will never creep into this organization that there will be any let-up in aggressive methods, which might suggest that when business is good there is no occasion for work and when business is poor it is too hard to get.

We constantly have in mind that the American people are much more concerned in their own affairs than in ours, and if we should restrict our selling and advertising activities they will begin to forget us—and this would be our fault.

We are going ahead with the idea of increasing the present momentum in favor of our goods; and if conditions should turn face about, our dealers and ourselves will be in a better position to hurdle obstacles than if we originated a policy for each condition as it arose.



Prompt Boiler Deliveries – Now

Our workmanship and quality considered—the following offerings are exceptional. Subject to prior sale of materials we offer prompt delivery of the following sizes—72 in. x 18 ft., 72 in. x 16 ft., 66 in. x 16 ft., 66 in. x 14 ft. Smaller sizes, too, can be quickly handled.

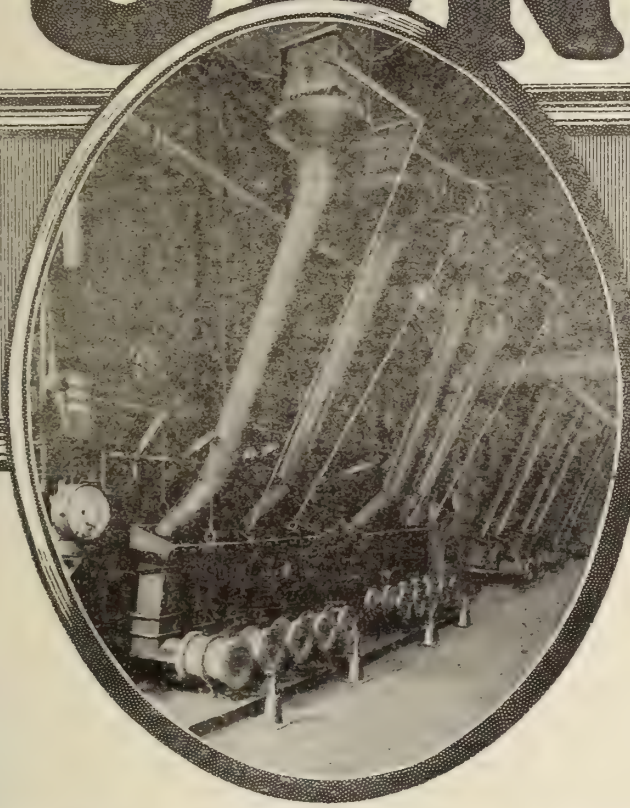
JONES



"A-C"

(Automatic-Cleaning)

STOKERS

Burn Any Available Coal at High Efficiency

WHEN the stoker is limited to one grade of coal, the plant is at the mercy of the mines and railroads. To-day, ability to burn the available coal means ability to burn any one of a number of coals. The Jones "A-C" (Automatic-Cleaning) Stoker will burn practically any coal from lignite to semi-anthracite.

In one plant Jones "A-C" Stokers are burning three parts coke-breeze to one of coal at 150% of boiler rating. "Bone coal," and war coal running 8,000 to 12,000 B T.U. as fired, is being burned at good efficiency in Jones equipped plants.

The Jones "A-C" burns a wider range of lowest grades of coal at highest efficiency because of the basic under-feed principle, originated by this company and given greater advantages by distinctive features found only in the Jones "A-C."

Simplicity and rugged construction, slight inclination of retorts, accessibility of parts, individual control of retorts and prevention of clinker on side and bridge walls, are some of the reasons why the Jones "A-C" will broaden your fuel market.

Manufactured by an old-established Canadian Stoker Manufacturer, newly re-organized to render a greater engineering service to Canadian power users. Write for extensive catalogs.

Minister: Hon W. R. Rollo — **Deputy Minister: W. A. Riddell, Ph.D.**

NOTICE TO STATIONARY AND HOISTING ENGINEERS AND STEAM PLANT OWNERS

Everyone operating a **Stationary** steam plant of 50 B.H.P. or over, and everyone operating a **Hoisting** steam plant working at a pressure of 20 pounds or over, irrespective of horsepower and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a certificate from the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

After January 1, 1920, all stationary steam plants in the Province of Ontario must be registered with the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

All applications should be mailed to the Chairman of the Board. W. C. McGhie, Department of Labour, 15 Queen's Park, Toronto.

NOTICE TO MANUFACTURERS, DEALERS AND USERS OF STEAM BOILERS

All steam boilers built in, or entering, the Province of Ontario, and boilers exchanged or repaired, are subject to Government Inspection as prescribed in the Steam Boilers' Act, 3 George V., ch. 61.

Before any work of repair or alteration is commenced on any boiler, notice must be sent to the Department stating the nature and extent of the repairs or alterations proposed to be made. If the Chief Inspector should consider such repairs or alterations of an extensive character, the boiler must be inspected in accordanee with the Regulations by an Inspector authorized under the Act.

All communications should be addressed to the Steam Boiler Branch, Department of Labour, 15 Queen's Park, Toronto. D. M. Medcalf, Chief Inspector of Steam Boilers.

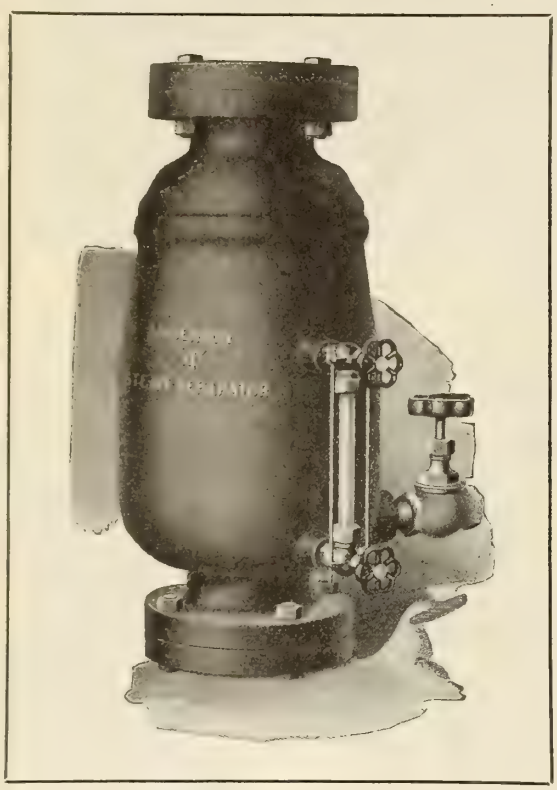
ANDERSON
Steam Separator



Make Breakdowns Things of the Past!

Time and labor are too expensive to stand idle. You can't afford to have any engine breakdowns due to accumulated moisture in engine cylinders and turbine casings.

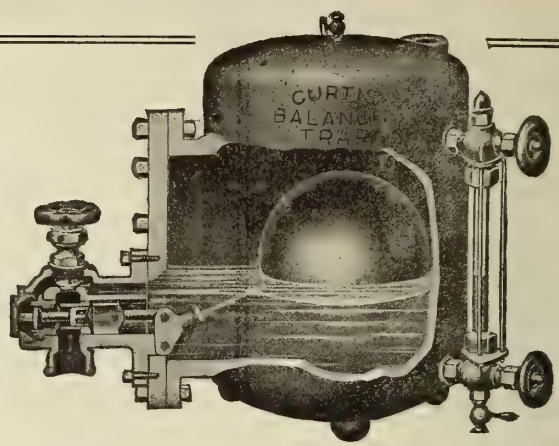
Breakdowns of this nature can be counted as things of the past in your plant when you install the Anderson Steam Separator.

The Anderson delivers **dry steam** under all operating conditions. The moisture is completely separated by the combined action of centrifugal force and the sudden reversal of high velocity steam current—and the moisture cannot be picked up again, when once separated.

A copy of catalog fully describing all Anderson Power Plant Specialties will be forwarded upon request.

The V. D. Anderson Co.
1935 W. 96th St. - Cleveland, Ohio

CURTIS Engineering Specialties



Five Superior Features of the Curtis Trap

1. A perfectly balanced valve.
2. An absolutely frictionless valve.
3. The valve can be removed without breaking a joint, starting a gasket, or taking out a bolt.
4. The valve being frictionless and balanced, the whole power of the float is available for opening and closing the valve.
5. Each trap will operate perfectly on pressure varying from one to 250 lbs.

Write for 1920 Catalog of Curtis Engineering Specialties. Canadian funds are accepted at par at Montreal.

In Public Buildings

Municipal engineers **demand** efficiency—and **insist** on economy of operation. Power plant equipment, to secure the approval of public engineers, must measure up to the **highest** standards.

This 22" COPPUS Turbo Blower in the City Hall at Montreal, Canada, has been burning bird's-eye with economy, and holding steady steam pressure without difficulty for many months. Here, as in thousands of plants the world over, COPPUS Blowers burn cheap coal, save time, labor and money, and greatly increase plant efficiency.

That COPPUS Blowers are recognized as leaders in their line is evidenced in the fact that three-fourths of all the blowers made in America bear our trade-mark. Ask our engineers to show you how "COPPUS Equipment can save **you** money." Write for Blower Catalog.

COPPUS TURBO BLOWER

The Fuel Situation!

How to Meet It!

With a coal famine staring us in the face, and the clean grades of coal almost off the market, it is essential that your boilers be equipped so that you can burn any grade of coal which you may have to use during the coming winter.

With COPPUS BLOWERS you can burn those cheap grades of fuel which it is impossible to burn with natural draft, and in addition, you can burn them more efficiently than you can the better grades of coal with natural draft. If, however, you have on hand a large supply of high-grade coal, COPPUS BLOWERS, by producing more complete combustion, will burn these grades of coal with a saving of at least 10% of your fuel. COPPUS BLOWERS, supplying forced draft under the grates of a hand-fired boiler, produce practically the same conditions of combustion which are secured in large Power Plant installations where expensive forced draft stoker equipment is installed.

On the other hand, consider the saving which can be secured by burning the cheap grades of fuel with COPPUS FORCED DRAFT as compared with the cost of burning the high grades of fuel by natural draft.

For example, if you are now burning ¾ Lump Bituminous Coal it will cost you to-day $14.75 per ton on the cars at Toronto. By installing COPPUS BLOWERS you can burn 80% of Birds-eye or Anthracite screenings at $6.00 per ton and the remaining 20% of Bituminous Slack at $13.50 per ton, so that the average cost to you would be $7.50 per ton for the mixture, OR A SAVING OF $7.25 PER TON, as compared with the cost of burning straight ¾ Lump Bituminous coal.

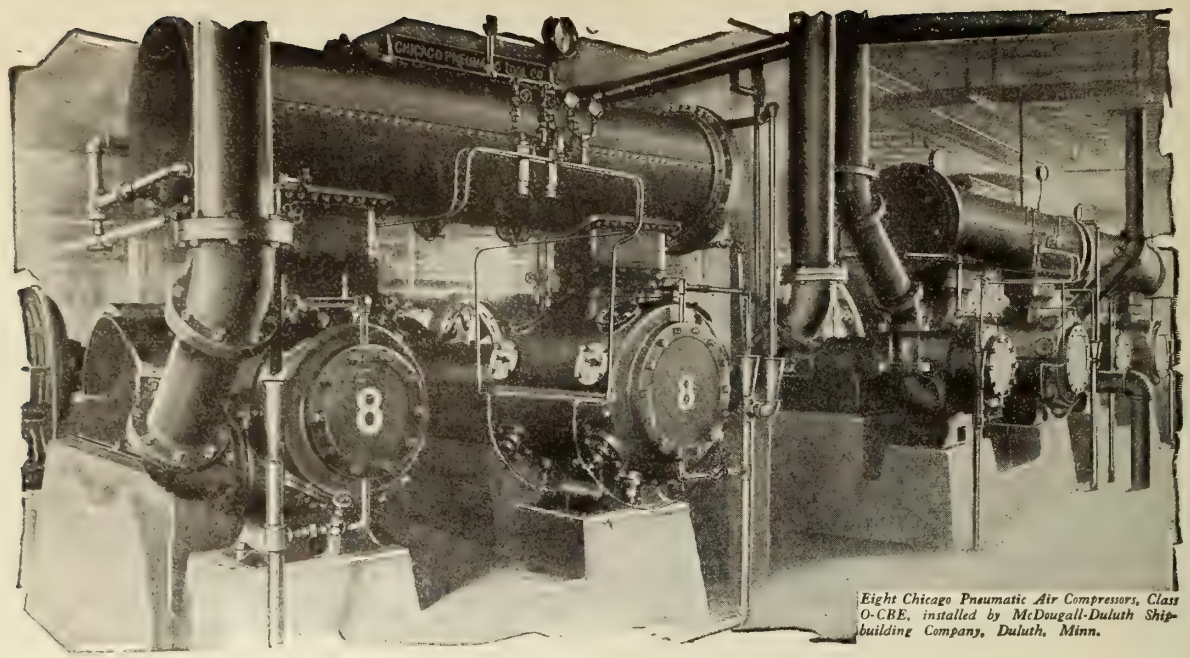
TORONTO



Eight Chicago Pneumatic Air Compressors, Class O-CBE, installed by McDougall-Duluth Shipbuilding Company, Duluth, Minn.

Real endurance is *continuous* performance

"Napoleon would often, when on a campaign, remain for days without taking off his clothes"

COMPARED to Napoleon's energy on the plains of Champagne, is the unyielding endurance of Chicago Pneumatic Air Compressors.

Many Chicago Pneumatics, after serving *continuously* over periods of five to fifteen years, are still delivering *dependable* air power.

Contributing to this faithful performance is the Simplate flat-disc indestructible valve. Over 500,000 Simplates in use have delivered unfailing service since the day they were assembled at the Company's plant. Their simple, fool-proof, rugged yet light-weight construction is responsible for this record.

Other C-P economy-features are: Exceptionally large bearing surfaces, totally enclosed frame construction, automatic lubrication, automatic regulation under varying loads, and modern construction throughout on all sizes and types of the complete line.

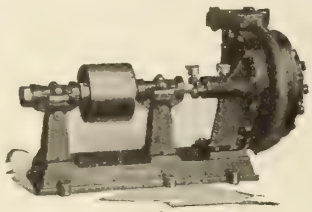
AMERICAN-MARSH PUMPS

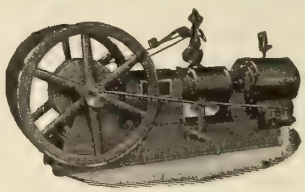
SIMPLE **RELIABLE** **EFFICIENT**

The American-Marsh steam pump is an improved form of the famous Marsh Pump which has been on the market for over thirty years, during which time over 150,000 have been manufactured and sold.

The American-Marsh Pump has no internal stuffing boxes, no tappets and no slide valves. The auxiliary valve is of the semi-rotative disc type of an improved design. The main steam valve is of the balanced piston pattern, assuring highest efficiency. The water ends have large valve areas and are fully bronze fitted, including solid bronze piston rods and bronze removable water cylinder bushings.



American-Marsh Centrifugal Pumps are made with the same high grade of material and workmanship which characterizes the construction of the steam pumps. They are made in all sizes up to 12 inch, both single and two stage for heads up to 250 feet.



The line also includes—

Power Pumps
Deep Well Engines
Air Compressors

Jet Condensers
Dry Vacuum Pumps
Boiler Feed Pumps

LINCOLN ARC WELDER

S.S. CHIPPEWA CRACKS CYLINDER

Repaired in 24 Hours

Saved Season's Tie-up by LINCOLN WELDING

THIS news item clipped from a recent issue of a Toronto daily shows exactly what Lincoln welding will accomplish.

Every plant owner and every shipowner should read this article. We will be glad, indeed, if you will communicate with us for further information about Lincoln Electric Welding.

REPAIR WONDERS ARE DONE ON CHIPPEWA

Electric Welding Process Puts Steamer Rapidly Into Commission.

The steamer Chippewa of the Canada Steamship Company's fleet is lying at her dock at the foot of Yonge street to-day undergoing repairs, which are being performed by the same method as was used to get the interned German liners into commission during the war.

It will be recalled that the German crews damaged their ships to prevent them being used by the allies. In most cases cylinders were cracked. The Germans expected that it would take years to get them in commission again, and this view was generally accepted until an engineer, who was consulted, declared that the repairs could be made speedily by the new process of electric welding. As a result the ships were in commission in a few weeks and helped to win the war.

The Chippewa, having yesterday developed a small crack in her cylinder an emergency call was sent to the Lincoln Electric Company, 136 John street, who are experts in electric welding. The work of repair began at six o'clock last night, continued all night, and will if is expected be completed some time to-day when the Chippewa will be ready to go back on her regular run. It is said that by previously known processes the repairs would have probably involved putting the boat into drydock and going out of commission for the rest of the season.

A truck carrying the power engine operating on the dock beside the Chippewa attracted the attention of all lake-front visitors to-day. From this truck wires led the current to the scene of operations, in the interior of the boat.

Electric welding is one of the most interesting of the new industrial processes. It has come into use in Toronto only within the last year or two, but already a large number of important firms have installed electric welding equipment and staff.

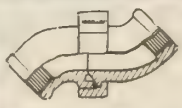
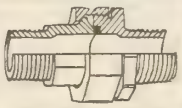
"LOOK FOR THE NAME ON THE NUT"

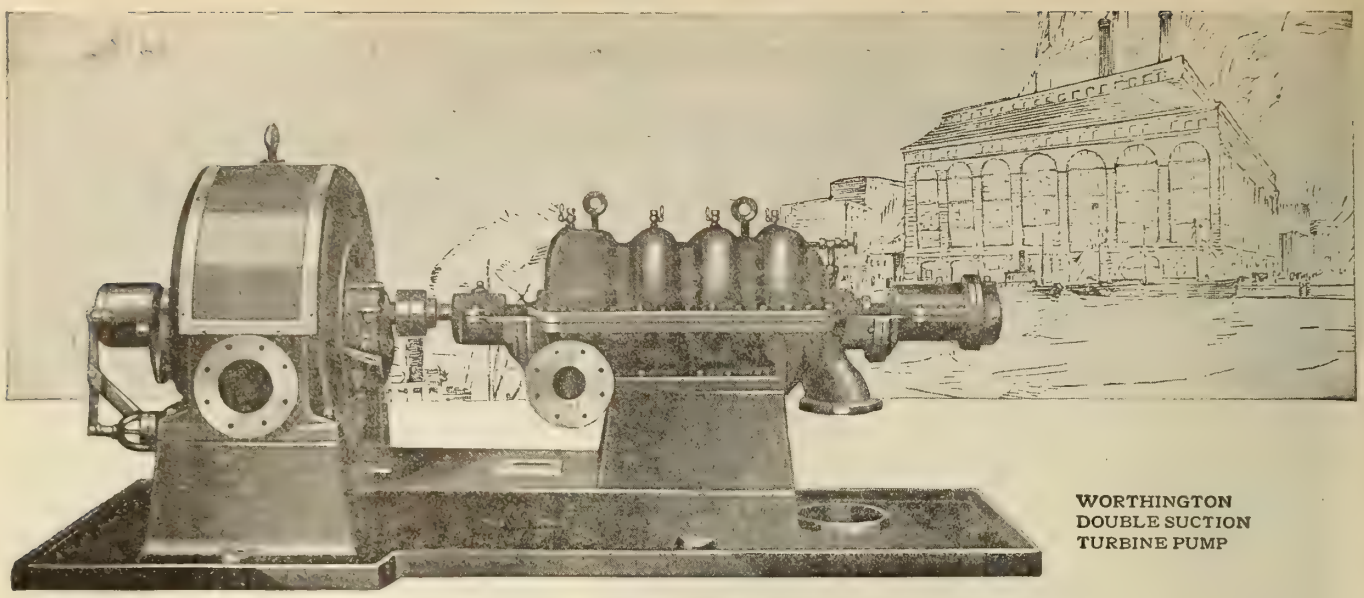


Jefferson Swing Union allows connections, ranging from a slight offset up to 90 degrees, and many angle connections.

Union Elbow, all female. Takes the place of a straight union, nipple and an elbow. Also made male and female.



All Male Union. Saves two pipe joints between two female threaded parts.



WORTHINGTON
DOUBLE SUCTION
TURBINE PUMP

Worthington Centrifugal Boiler Feed

TO satisfy the need for a centrifugal boiler feed pump that is free from end thrust, Worthington offer their Double Suction Turbine Pump for boiler feed.

Worthington have designed and built into this centrifugal type pump a distinctive hydraulic balance port which inhibits end thrust even when the pump becomes old. And this continuously good, long service has made Worthington Double Suction Turbine Pump leader in its field and worthy representative of the engineering skill and constructive ability of the 80 years old Worthington organization.

This pump is one of the varied Worthington line of power plant apparatus that has successfully satisfied over 200,000,000 boiler horse power since 1840.

Other Worthington Products:
Steam, Power, Centrifugal and Water Works Pumps. Meters, Oil Engines, Condensing Machinery, Air Compressors, Vacuum Pumps and Water Wheels.

To further enlarge their service, Worthington have acquired the good-will and mechanical equipment of the Platt Iron Works, Dayton, Ohio, for manufacturing Oil Mill Machinery, Hydraulic Turbines, Feedwater Heaters and High Pressure Air Compressors.

De Laval Oil Purifiers Provide Safe Lubrication for Turbines

Oil used to lubricate direct-connected or geared turbines inevitably picks up a large amount of foreign matter such as particles of metal, dirt, sand and water. If allowed to remain in the oil, these impurities cause the early destruction of the bearings and gear teeth.

All such impurities are instantaneously removed from lubricating oil by the DeLaval Oil Purifier. Core sand, red lead, pipe scale and pipe burrs, which frequently cause so much trouble when new plants are started up, are also effectually removed from the oil.

Waste of oil is entirely eliminated by the De Laval Method of Purifying Oil by centrifugal force. The dirty oil in the oiling system is pumped into the rapidly revolving bowl of the Purifier where all impurities are removed, the clean oil being delivered back into the lubricating system. The heavier solids remain in the bowl and the lighter solids are sludged out through the waste spout.

This self-sludging feature of the De Laval Purifier enables it to operate efficiently on long, continuous runs without stopping to clean the sediment pockets. When this becomes necessary, it is quickly and easily accomplished.

De Laval engineers have evolved a number of general types of De Laval Oil Purifier installations suited to most power plants. They will be glad to study your problem and recommend a type of installation to meet your particular needs.

Write to nearest De Laval office for Oil Purification Bulletin No. 100; also Crank Case Oil Bulletin No. 102.

HEAD OFFICE FOR CANADA - COLLEGE ST. (ST. HENRY), MONTREAL
TORONTO OFFICE, TRADERS BANK BUILDING

CANADIAN MACHINERY wants a representative in every town and city where there is a metal working plant or large machine shop.

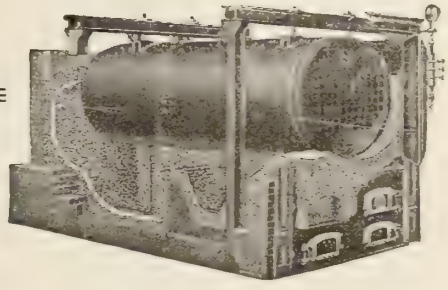
We require first of all the ability to demonstrate to mechanics the value of reading technical journals in general and CANADIAN MACHINERY in particular, and to secure their subscriptions.

Second—we want men who can tell news when they see it. Not necessarily men who can write, but men who are alert for news, and who will give us the facts, briefly and plainly.

We will pay you liberally if you can handle this work for us in your city.

Canadian Machinery and Manufacturing News

143 University Ave. Toronto, Ont.



For Furnace Linings and Baffles

That are easy to install—air and gas tight, that cannot crack, chip, spawl or peel off—no separate fire brick, no mortar joints and not affected by expansion and contraction.

BETSON'S TRADE MARK PLASTIC FIRE BRICK

is a plastic, unbaked fire brick material—made of the best fire clays and refractories—proportioned and mixed to withstand all strain, heat, gas and chemical action to which it may be subjected by the hardest usage. It outwears all other boiler furnace linings.

Write for informing pamphlet.

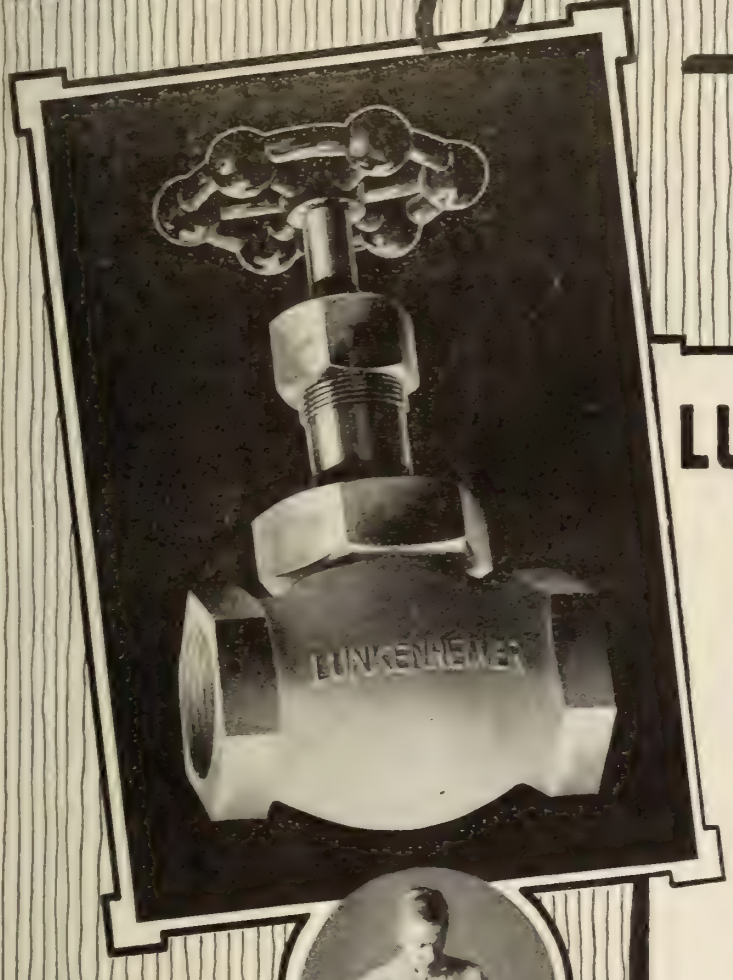
Superiority—unfailing performance—service

AMERICA'S BEST
LUNKENHEIMER
"QUALITY"
SINCE 1862



The original Regrinding Valve

LUNKENHEIMER REGRINDING VALVES

have firmly established their unparalleled merit by the successful results they have given through many years of satisfactory service.

The metal to metal seat—ground to a tight fit, forms the ideal seating surface to resist the wearing action of steam at high velocity. And the fact that the seating surfaces can be re-ground (an inexpensive operation easily accomplished) makes the renewal of parts wholly unnecessary.

Their extreme durability due to correctly proportioned parts, high quality materials and expert workmanship insure economy in maintenance.

Globe, Angle and Cross Valves with Inside Screw and with Outside Screw and Yoke; and Horizontal, Angle, Vertical and Swing-Check Valves for 200 and 300 pounds working steam pressure.

Specify **Lunkenheimer** and insist on their installation. Distributors of Lunkenheimer Products situated in every commercial centre.

Write for descriptive booklet No. 517—DC

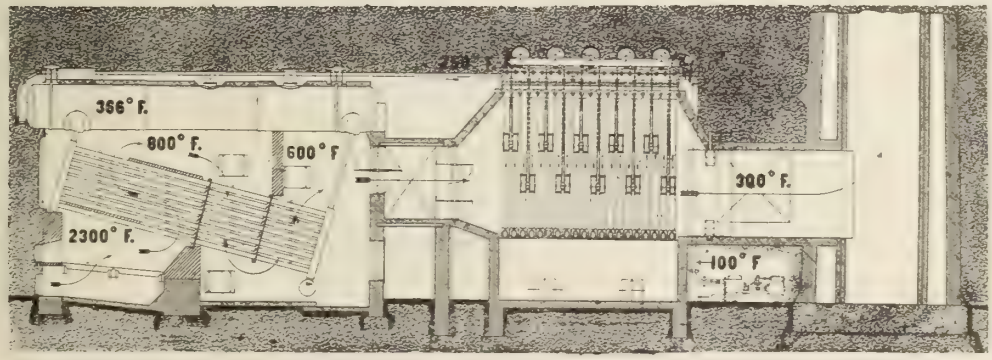
GREEN'S ECONOMISERS



A Saving of 13.6%

Green's Economiser "installation temperature diagram" showing a rise of 150° in feed water temperature above that of the feed water heated. This is not an unusual case, and under these conditions would show a saving of 13.6% based on 1% saving for each 11° increase in feed water temperature.
Modern economic operation of boiler plants demands that your boilers be operated above normal rating. This means higher exit temperatures on the flue gases.
Green's Fuel Economisers utilize this heat in the flue gases to heat the feed water under boiler pressure, which accounts for the fuel saving and also allows you greater boiler capacity.
Ask our engineers for data on economisers for your plant.

Elements Vital to Effective Superheating

THERE are certain basic engineering principles in the design and installation of superheaters, which when practised insure success.

Among these is the location of the superheater heating surface. The heating surface of ELESCO Superheaters is made up of small diameter steel tubing, affording its location in advantageous gas temperatures. This makes possible a large ratio of superheating surface, an even distribution to the flow of the gases, and a proper distribution of the steam through the superheater.

Furthermore, the small diameter tubing of ELESCO units makes it possible to distribute the heating surface so as to insure a free flow of the gases past the superheater.

A correct combination of these and other vital elements, are the basis of the success of ELESCO Superheaters.

These Points are Covered in Our Bulletin—Send for Your Copies

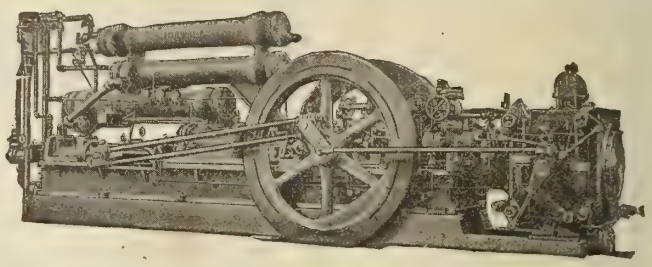
NORWALK
AIR & GAS · COMPRESSORS

Time-Proven

Wherever there is a point of strain or wear in a Norwalk Compressor there is the special quality—the excellence of materials and careful workmanship—to minimize operating stresses and insure continuous efficiency. It is this manufacturing policy which has given Norwalk Compressors their high standard of reliability.

The satisfaction derived from a Norwalk Compressor at the time of installation is only a foretaste of the complete confidence which grows with years of service.



A Four-Stage Compressor driven by Compound Corliss Steam Cylinders.

Our Bulletins on air, oxygen, hydrogen, acetylene gas or carbonic acid gas describe in detail the structural features which account for the famed Norwalk durability.

Write for those which interest you.

ANNUAL DIRECTORY NUMBER

POWER HOUSE

A semi-monthly newspaper devoted to the Generation, Transmission, and Application of Steam, Gas, Electric, Air and Water Power; and to the operation of Refrigerating Machinery.

Vol. XIII.—No. 20. Publication Office, Toronto—October 20, 1920 Published Semi-Monthly Canada, $2; U.S., $2.50 a year

The Plant That Keeps
Other Plants in the

Forefront of Progress

A standardization of the most advanced engineering practice that has eliminated the vulnerable points of ordinary undergrate blower construction that sooner or later show up in actual service, Coppus Turbo Blowers are a distinctive system that is adaptable to any installation requirements from the smallest to the largest.

Being the adaptation of the best in centrifugal pump construction to the extremely difficult service of boiler feed, Coppus Turbo Feed Pumps make available to power plants a rugged, dependable, economical centrifugal pump in units of 100 to 4,000 B.H.P.

Intensive scientific study plus the unusual facilities of this great Coppus plant, have made possible this triumph of industry, best appreciated by the power plant engineer who feels he has done with experimenting and who has the matured judgment to recognize that the best is always cheapest.

To enable you to make this careful investigation on the correct determination of which rests the profits of many years, we will send you without charge the Coppus catalogue.

Modern Power Plant Equipment

Since 1910 we have been representing in Canada, those manufacturers of power plant equipment whose products have become established as the **standard,** each in its particular line. You'll know them all by reputation.

To give **good service** has always been our aim. This we have accomplished by handling only quality equipment, by fairness and promptness in all things. For a combination of **quality** and **good service**—come to us!

Equipment We Handle

Taylor Stokers
Kellogg Chimneys
Terry Steam Turbines and Reduction Gears
Skinner Uniflow Engines
Sims' Heaters
International Water Softeners and Filters
Hays' CO_2 Apparatus
Economy Sump Pumps
Dayton Dowd Centrifugal Pumps
Dean of Indianapolis Steam Pumps
Rumsey Rotary and Triplex Pumps
Nash Vacuum Pumps and Air Compressors
Coppus Turbo Boiler Feed Pumps and Under-grate Blowers (see front cover)
The Brown Instrument Co. Indicating and Recording Instruments

Watch for full details of each of these lines, which will be treated individually in future issues of Power House.

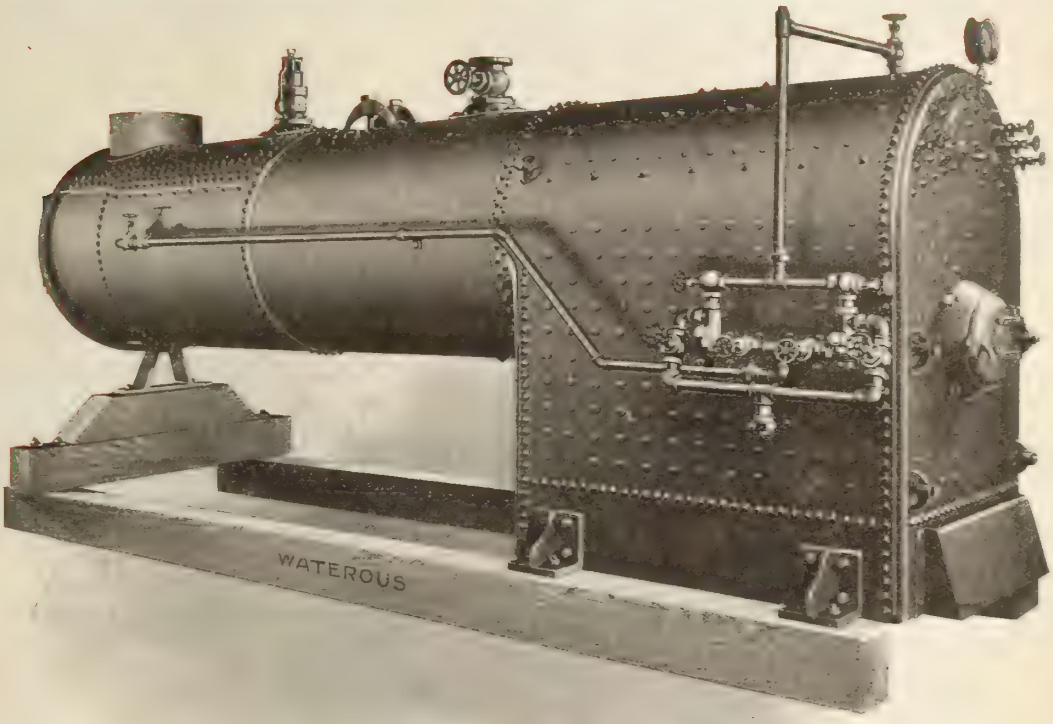
Stationary and Portable Boilers

Boilers in Stock for Immediate Delivery

1—54x14 Horizontal
2—60x14 "
14—72x18 "
4—66x16 "
2—40 H.P. Locomotive



ECONOMY in fuel consumption, ease and convenience in operation, absolute trustworthiness—these are outstanding features of Waterous stationary and portable boilers. As with all other Waterous products, every part is rigidly factory tested to withstand stress far in excess of that at which they are rated, thus ensuring a high, positive safety factor.

We build different styles of boiler settings, designed to best handle various fuels. Waterous boilers assure you the highest possible efficiency. Let us specify on your requirements.

ROBB POWER PLANTS

For Quality Equipment

We specialize in the design and construction of power plant equipment. Our engineers are prepared to investigate your problems and advise on the most economical machinery for your needs.

We can supply Corliss, Slide-Valve, Vertical, Horizontal, Simple and Compound Engines, and Water tube, Return tubular, Improved Scotch Marine, and Portable Boilers.

Robb Equipment is known to engineers and power plant superintendents for its long and dependable service, standard quality and modern design. When you are in the market—remember it will pay you to purchase equipment that has won the confidence of leading engineers.

DURABLA
TRADE MARK REGISTERED

STRENGTH—GOODNESS—QUALITY

Performance Facts of Durabla Gasket Material

Tight joints are made and maintained by DURABLA under the following severe services and conditions:

Steam:	275-300 lbs. pressure; 275°-300° superheat.
Oil:	Pressure still joint re-made over 160 times.
Gasoline:	Cylinder heads of gasoline engines and pumps.
Acids:	All acids that can be carried in pipe lines.
Water:	Equally satisfactory with temperature of 40° or 210° F., at any pressure.
Ammonia:	Both absorption and compression systems of refrigeration.
Air:	Air lines and cylinder heads of compressors—all types.

One Standard material for all gasket work—Sold on a Service Basis

DURABLA is sold in sheet or gasket form and the trade mark is stamped all over the material.

Distributors for Canada: The Canadian Fairbanks-Morse Company, Limited

DURABLA

Less Wear and Tear

IMPERIAL Lubricants keep plant machinery running smoothly, reducing friction and consequent power loss.

Their regular use prolongs the life of your equipment, and increases its efficiency.

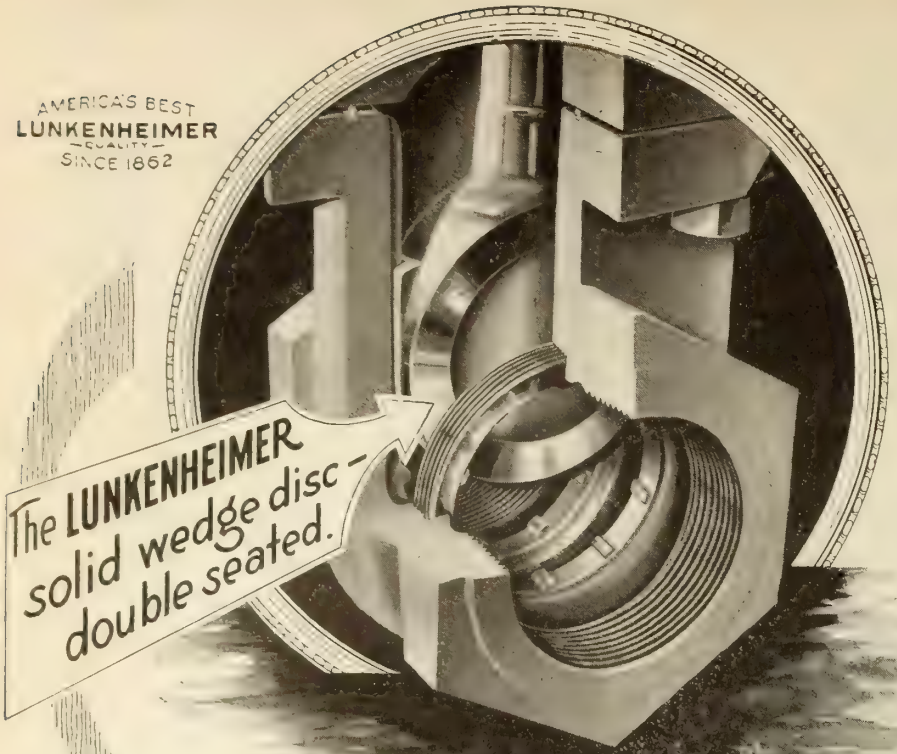
Imperial Lubricants are graded to meet the varied requirements of every type and make of machine. Each grade of oil is refined to the same exact, scientific standard. Ample supplies—every grade—carried in stock near you.

Many Imperial Oil customers voluntarily report savings as high as 35% in lubricating oil bills when following our recommendations. That's worth while economy that goes along with increased capacity and lowered depreciation costs.

Imperial Lubrication Engineers will gladly make it their business to see that you get full value from the lubricating oils you use. It will pay you to call in the Imperial Oil man and have him prescribe for your plant.

Write to 56 Church Street, Toronto, for more information.

AMERICA'S BEST
LUNKENHEIMER
—QUALITY—
SINCE 1862



LUNKENHEIMER "VICTOR" GATE VALVES

Fig. 602

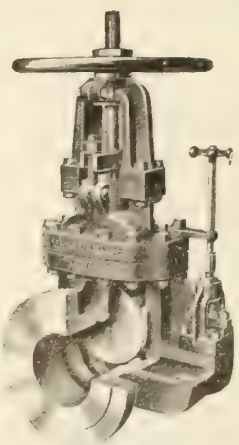


Fig. 894

have a solid wedge disc which seats on rings threaded into the body in exact alignment with the disc faces. The disc is guided and travels practically a closed position before coming in contact with the seat ring faces. This construction eliminates the "dragging" of the disc across the seats and the consequent wear prevalent in valves employing loose parts.

The generous proportion of all parts and the high quality materials insure ample safety factors for all service conditions.

An exclusive Lunkenheimer feature is the gasket between the body and bonnet-flanges, consisting of a seamless copper wire partly embedded in the body flange. It cannot blow out and is practically indestructible.

The bearings are bushed to insure long life to the wearing parts, and to further enhance their durability as a whole, all the parts are interchangeable.

Made with Inside Screw Stationary Stem and with Outside Screw and Yoke, Rising Stem in Bronze, Iron and Steel for pressures up to 350 pounds and temperatures to 800 degrees F.

For **Safety, Service** and **Economy,** specify LUNKENHEIMER "VICTOR" GATE VALVES and insist on their installation.

Distributors of Lunkenheimer Products situated in every commercial center.

Nonpareil Grates

The Enemy of High Fuel Prices

When big manufacturing firms install new equipment they never jump at conclusions or take anybody's word as to its merits. They have their own experts investigate first. This is exactly the course taken by the following well-known firms before installing NONPAREIL SHAKING AND DUMPING GRATES.

H. J. Heinz & Co., Leamington, Ont.; 7 Sets
Canadian Allis-Chalmers, Limited, Toronto; 25 Sets
Simmons, Limited, Toronto; 2 Sets

Before any of these companies installed NONPAREIL GRATES they satisfied themselves of their efficiency and economy—that they would give perfect combustion, improved service and would SAVE FUEL, and otherwise live up to the claims we make for them. When firms like these place their stamp of approval on Nonpareil Shaking and Dumping Grates they must surely possess advantages.

Attractive Trial Offer

You are at liberty to order a set of NONPAREIL GRATES and test them out FREE of charge. We guarantee a saving of at least 10 per cent. on your fuel consumption. This is fair and reasonable—why hesitate?

Firebrick Work

Some of the largest power plants in Ontario have had their Firebrick Work done by "Safety First" Sexton and his staff. Quality work only! Remember, Nonpareil Grates and Sexton's Brick Work make an unbeatable combination.

REPAIRS—Grate Bars supplied, and Repairs made to all kinds of Shaking and Dumping Grates.

Vulcan Soot Cleaners

As Dividend Earners

HERE is a very conservative estimate of what may be expected from an average installation of Vulcan Soot Cleaners as computed by Messrs. Hale-Stephan Co., Vulcan representatives and engineers and contractors for power plant equipment at Cleveland, Ohio. This estimate is based on an actual case at the request of a Results Engineer in charge of a widely known public service corporation in Ohio. In this case a temperature drop of only 50° F. is assumed.

As a basis for computation, the Results Engineer assumed a 5 lb. consumption of coal per boiler horsepower per hour. The estimate follows:

"Assuming a 400 H. P. boiler—Stirling, 3 pass, operating at 150% rating. Average CO_2 equals 9% or 130% excess air, or about 19 lbs. air per pound coal burned. Assume about 5 lb. coal burned per horsepower hour.

600 boiler H. P. equals 150% rating.
5 lbs. coal per H. P. hour.
3,000 lbs. coal burned per hour.
19 lbs. air per lb. coal.
57,000 lbs. gas per hour goes through boiler.

Assume soot cleaner will give an average flue temperature drop of 50° F. Specific heat of flue gas equals about .25.

57,000 × 50 × .25 equals 712,500 B.t.u. per hour through soot cleaner. One boiler horsepower equals

33,478 B.t.u. per hour.
712,500 ÷ 33,478 = 21.3 boiler horsepower gained.
21.3 ÷ 600 = 3.55% gain due to soot cleaner per hour.
One ton of coal saved per day of 20 hours.

Any combustion engineer will at once see that both the basic assumption and the resulting estimates are very conservative; anyone acquainted with actual results from the use of Vulcan Soot Cleaners knows them to be far below the average.

Either Canadian office will gladly send descriptive Bulletin of Vulcan Cleaner for your boilers upon request. Or address the home office.

WEIR

Pumps for Feed and Other Duties

The slow, steady, powerful strokes of Weir Pumps inspire a confidence fully justified by the service of the 65,000 Weir Pumps at work all over the world.

Weir Pumps are designed to work at moderate speeds. Thus they last longer and work more satisfactorily than high-speed running pumps.

The boiler is the heart of the ship or power plant. Any possibility of a stoppage is exceedingly serious. Therefore it pays to use pumps whose past and present performance proves that they are to be relied upon at all times.

Full particulars of Weir Pumps and other auxiliaries will gladly be furnished upon request

Genuine British Oak Tanned

LEATHER BELTING

The Choice of Many Power Plants

The large, efficient power plants do not choose the belting upon which they depend for their power transmission by any haphazard method. They investigate and weigh carefully the advantages of each brand.

D. K. McLaren's Leather Belting is made of the **backs** of the finest steers and is **Genuine British Oak Tanned.** Every workman is highly skilled each in his particular way. This is **why** D. K. McLaren's Belting is good!

Finally, many of the largest power plants throughout Canada choose D. K. McLaren's Belting to maintain their efficiency. And, after all, the service which this belting renders its users is the greatest proof of its quality.

Ask us for the names of some of these plants. Then write them and secure their impartial opinion.

Bear this Maple Leaf in mind when purchasing belting. It is your guarantee of dependability —a guide to efficient belting service.

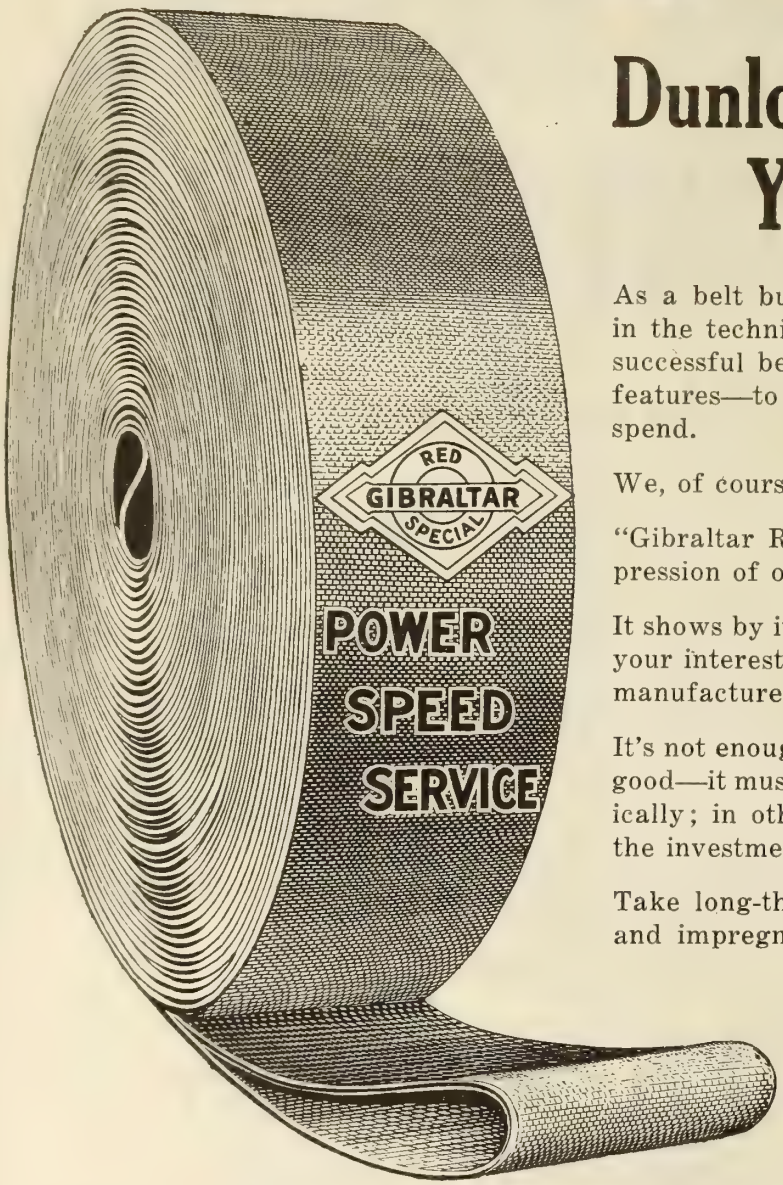
The "Long Service" Belting



Dunlop Belts Protect Your Profits

As a belt buyer you are not so much interested in the technical features which go to make up a successful belt, as you are in the benefit of these features—to realize full value for the money you spend.

We, of course, are, naturally, interested in both.

"Gibraltar RedSpecial" Belting is a tangible expression of our interest.

It shows by its performances just how we consider your interests when you buy a product of Dunlop manufacture.

It's not enough to let it go out of our plant looking good—it must act well, and serve well and economically; in other words, show a good dividend on the investment you make.

Take long-thread, tough cotton, carefully woven and impregnated with a high-grade rubber friction; build it up ply upon ply and cure and stretch it in the Dunlop way—then you have "Gibraltar RedSpecial."

It's a Transmission Belt built to deliver.

Its stretch is practically nil—because of the way it is made.

It won't slip because of its frictioned-surface, which gives great clinging power.

Our Belt Department will be glad to serve you.

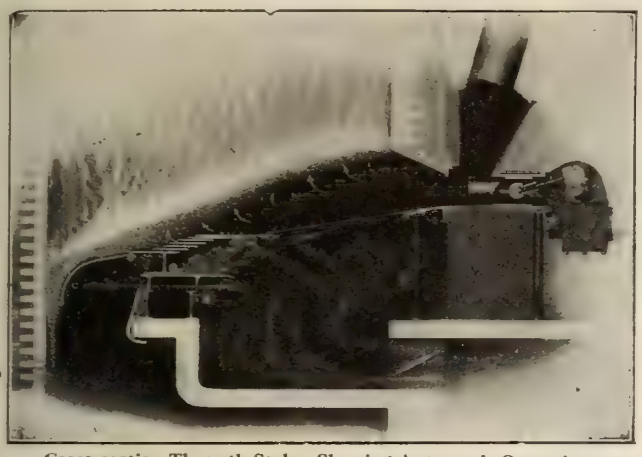
BURN ALL GRADES OF COAL



Cross-section Through Stoker Showing Automatic Operation

No device has shown itself better adapted to burn any available coal than the

RILEY UNDERFEED STOKERS

Low-grade coals—those high in ash—in sulphur and clinker-forming qualities—can be handled successfully for the following reasons:

1. The moving grates keep the clinkers broken up—combustion is intensified—the fuel bed is always active, even and in a homogeneous state.

2. The rocker dump, with its combination of vertical thrust and rocking motion, grinds up—discharges the ash continuously and automatically—keeps the fire clean and the bridge wall free from accumulations.

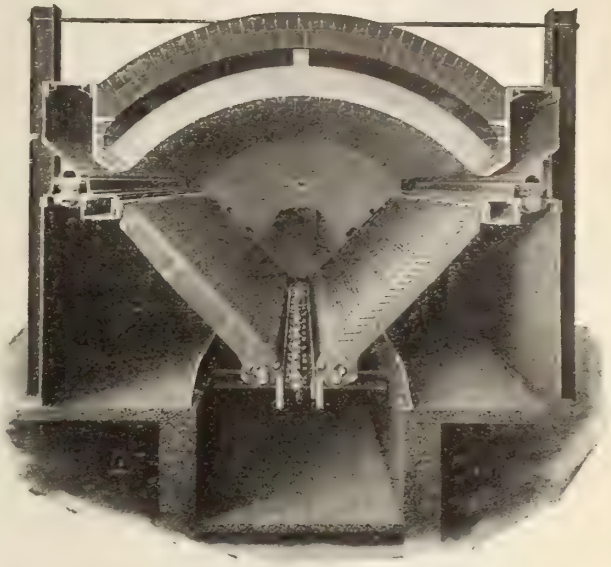
3. The underfeed feature makes possible high capacity and instant response to overload demands.

Our engineers will be glad to acquaint you with the wide range of fuels now being handled by the RILEY UNDERFEED STOKER under many varying conditions.

Write for Catalog HM-10

Sanford Riley Stoker Co.
Worcester, Mass.

MURPHY AUTOMATIC FURNACES



WHEN COAL WAS CHEAP —AND NOW

The Murphy Furnace earned its way forty years ago when coal was "dirt cheap." Think how much more quickly it can pay for itself when it saves 15 to 25 per cent. of the price you pay for coal to-day!

Murphy Furnaces bring to the smaller plant the economical advantages of the larger plant without resorting to forced draft, so the money you save on auxiliary equipment goes far toward paying for their installation.

Under present conditions it is economy to equip even the smaller boilers with Murphy Furnaces—for it saves your fuel and enables you to burn the poorer grades of coal that everyone gets these days.

If your boilers are 50 H.P. or larger you should get in touch with us. Send for Catalog HM-11 and see how easily the Murphy Furnace can be installed under any type of boiler.

For information on Riley Underfeed Stokers for large boilers, see last month's advertisement—or send for Riley Stoker Catalog HR-11.

MURPHY IRON WORKS
DETROIT MICH. U. S. A.

Hose Which Resists Wear

WE have records of Goodyear Air Drill Hose giving from 18 months' to 2 years' service--though the life of most air drill and pneumatic tool hose is comparatively short.

Dragged over rocks and steel girders, beaten by ore and building materials, the cover on air drill or pneumatic tool hose is greatly responsible for the life of the hose.

The extra heavy cover of white rubber, tough as a tire tread, with which Goodyear has fitted Air Drill and Pneumatic Tool Hose resists wear to a remarkable degree.

Inside this hard-wearing cover is a special, oil-resisting inner tube, and a fabric of such strength that Goodyear Hose is very much lighter than ordinary hose of the same strength.

In the same painstaking way, Goodyear has solved each individual hose problem—whether for steam, water, air, acids, or other substances. The creation of hose which would successfully withstand the strain of *present* industrial conditions was the task Goodyear scientists faced and solved. The hose problems in your plant can be greatly reduced with the help of Goodyear data and a Goodyear trained man. This service is without charge. Just phone, wire or write the nearest branch or Goodyear Mechanical Goods Service Station.

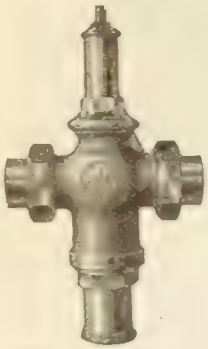
WHY "MASON"?

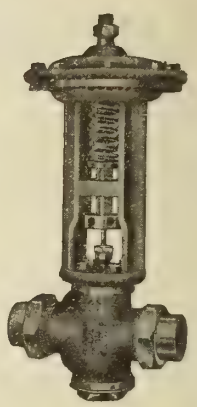


Mason Standard Bronze Reducing Valve

THE splendid reputation of the Mason Engineering Equipment is not the result of an accident, but the expected outcome of forty years of persistent effort backed by large capital and superior manufacturing facilities.

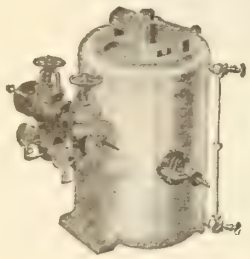
They hold the first place to-day because their merits entitle them to that position.

No other devices work so accurately, wear so long, nor accomplish their purpose so fully as the Mason. Once installed they are always demanded thereafter, and thousands of manufacturers absolutely depend on these devices working in many critical locations and find them satisfactory. This is where Mason Service comes in. We have at your service a staff of engineers, specialists in the application of our devices. Their job is to see that you do not throw money away on unsatisfactory equipment, and to help you to choose equipment that will do the work required.

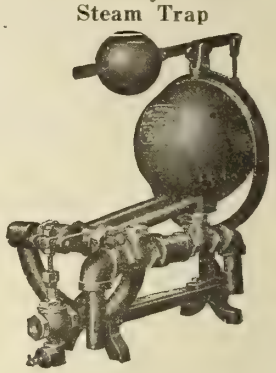


Mason No. 55 Pump Pressure Regulator

Reilly Feed Water Filter and Grease Extractor



New Bundy Return Steam Trap



We are very glad to hear from engineers who have a difficult problem in pressure regulation, engine or pump control, damper or blower regulation, or condensation drainage or returns. We have yet to hear of a problem, to which there is a possible solution, that we cannot solve.

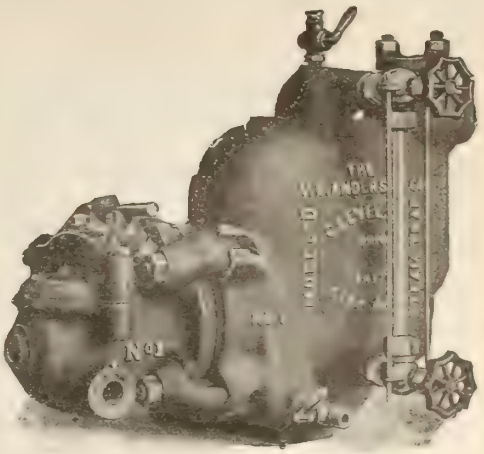
The Anderson

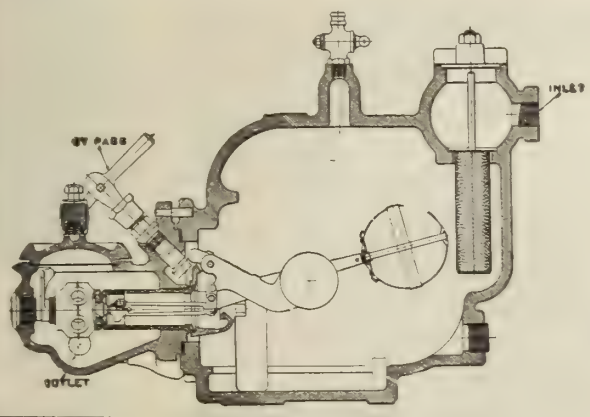
Model "D" Steam Trap

Accurate in Every Detail



The Anderson Model "D" Steam Trap is accurately designed and carefully made of materials best suited for the purpose. Every part is interchangeable.

The valve is locked with at least three inches of water at all times, thus making the escape of live steam an impossibility.



The trap will lift water at any pressure five pounds less than the pressure at the trap.

It is possible to ascertain whether the valve is functioning properly by glancing at the glass water gauge.

Both the valve and valve seat can be removed without breaking a steam joint or pipe connection.

Full particulars of these and other outstanding features of the **Anderson** will be gladly forwarded upon request.

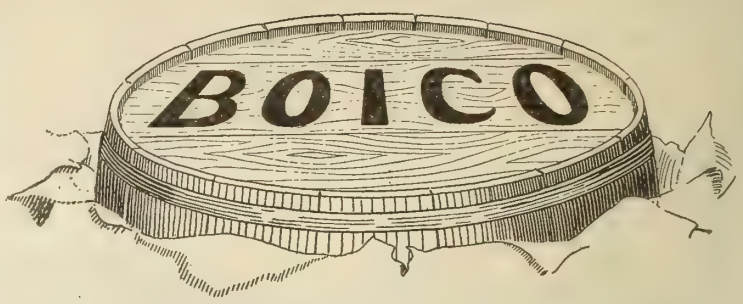
The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.



Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.**

BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.

Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

Toronto - - Canada

"Cyclone" Hoists *and* "Matchless" Trolleys

Lighten Labor *Lessen Costs*

For the same reason that you put in any kind of labor-saving equipment, you should put in the kind that saves **the most labor.** In chain hoists that means the "Cyclone."

The power applied to the hand chain of the "Cyclone" is multiplied in a different way from that used in any other hoist. The gears used are extra large, accurately cut, mounted on graphite bronze or roller bearings, and several teeth are always in mesh at every point where the load is transmitted.

There is less friction—no vibration—just a smooth, easy motion that raises the load with minimum effort yet maximum speed. The "Cyclone" is easier on itself as well as on the man using it and, as a natural consequence, it far outwears any other hoist.

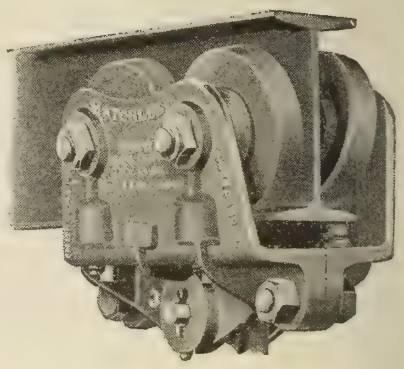
Made in sizes from ½ to 40 tons—every size a single, self-contained, compact unit.

For conveying the hoisted load with similar easy smoothness, hook the "Cyclone to a

"Matchless" Trolley

This trolley has flangeless track wheels and vertical adjustable guide rollers, so that it works freely on curves as short as 18-inch radius. Each size is adjustable for three sizes of standard I-beams. Hardened steel roller bearings on the track wheels reduce friction and lengthen service.

Made plain as illustrated, and geared.
Capacities from ½ to 12 tons.



Made by Chisholm-Moore Mfg. Co., Cleveland, Ohio.

Three Months of Continuous Operation at High Capacity

Boilers were kept on the line continuously for over three months, loads varying from 75% of rating to 250%.

Service that Costs Less Per Year

WHAT is the cost of a mechanical stoker? This question is answered by another question: What is the cost of stoker *service?*

In the face of unprecedented coal and labor costs, *"service"* has become the big word in Canadian power plants. Briefly, it means lowest cost per ton of coal fired. And lowest cost per ton of coal fired is only possible where a real high-duty stoker is installed.

Foremost in importance, and therefore foremost in the saving effected by the Jones "A-C" (Automatic-Cleaning) Stoker, is economy of fuel.

The Jones "A-C" saves coal as a result of the perfected application of the Jones under-feed principle of correct combustion, and because of its ability to burn all grades of coal, consequently the cheapest *local* coal.

The Jones costs less per year because it will carry the heaviest power burden endlessly day and night; without replacements and the shut-downs that replacements entail; without repairs and the expense that repairs involve; at highest efficiency and the economy that always follows.

The plant records opposite establish the fact that the heavy overloads which the Jones "A-C" meets almost momentarily can be carried continuously over periods of months, not merely during carefully conducted test periods of short duration. The names of these plants will be furnished on application.

The cost of the Jones "A-C" is no greater than that of any other multiple retort stoker of the same general class. But it pays a greater dividend in annual economy.

The services of the engineering organization described on the next page are at your disposal.

THE Under-Feed Stoker Company of Canada, Limited, is an old-established organization, newly reorganized for the purpose of putting before industrial Canada an engineering service of the broadest possible scope.

To the wealth of experience gained in installing the famous Jones Standard Stoker in Canadian plants for over a quarter-century, has been added the engineering resources of the well-known Under-Feed Stoker Company of America —a business institution of equal tenure.

Jones Stokers are made in Canada by Canadians, and are sold for Canadian money at par.

Write for extensive catalogs describing the new Jones "A-C" Stoker and "Standard" Stoker

Giant oil engines pay for themselves

GIANT Oil Engines cut down monthly power bills sufficient in most cases to return their initial cost within a short time.

The cost of oil for fuel is low. Giant Oil Engines burn most efficiently the lower grades of low-cost fuel oil.

Through automatic regulation they prevent waste of fuel and power and eliminate the human factor in obtaining power efficiency.

Their sturdy, simple construction—free from valves, magnetos, carburetors, wiring and other complicated devices—prevents breakdowns and the expense of frequent replacements.

Power costs of ½ to ¾ cent per horse power hour are common amongst Giant Oil Engine users.

Performance records are available showing the dependability and operating economy of Giant Oil Engines under service conditions similar to yours.

Ask for bulletin.

Giant Semi-Diesel Oil Engines are built in capacities from 12 to 200 H. P., both single and duplex types. They embody such important features as box-type crosshead construction, hot liner ignition, and totally enclosed frame and automatic lubrication.

THE REES RoTURBo

A Centrifugal Pump for Any Service

IN the "Rees-RoTURBo" we have the very latest development in centrifugal pump design. The disadvantages of the ordinary pump have been entirely overcome and it meets perfectly the conditions of to-day for high efficiency.

The fluid velocities are low, reducing friction losses to a minimum, and there is no wear even from gritty water, and high permanent efficiency is maintained. This means that the "Rees-RoTURBo" is ideal for multi-stage operation and may be said to be a pump for any service.

Should there be any point on which you would like to be enlightened, our engineering department is always at your service and without any obligation on your part we heartily invite enquiries.

The Utilization of Low Grade Peat For Fuel

Although the Following Paper Read Before the Royal Dublin Society by Professor Purcell, A. M. Inst. C. E., Deals With Irish Peat It is of Interest to All Who Study Low-Grade Fuel Utilization

PEAT in an undrained bog contains anything from 90 to 95 per cent. of water, and this statement is equally true whether we are dealing with Irish peat or peat in other countries, with the exception of some deposits in Italy, which are specially situated. By thoroughly draining the bog the water content may be reduced to some value between 91 per cent. and 88 per cent. We see, therefore, that the proportion of solids in the raw material will not exceed 9 to 12 per cent., and that the handling of such a low-grade material must present a serious economic problem.

When we compare a peat with 95 per cent. of water to one with 90 per cent. of water at first glance it looks as if the difference were only slight, but if the statement were put that in the first case you had 5 per cent. of dry peat and in the second 10 per cent., or that the "water ratios" or the relative proportions of peat and water were 19 to 1 in the first and 9 to 1 in the second, it would be quite obvious that the second peat contained twice as much valuable matter as the first. A glance at the diagram—Fig. 1— will make this clear. The weight of anhydrous peat or dry peat substance present is assumed to be the same in each case, and is shown by a cross hatched square representing one unit of peat by weight, and the proportion of water is shown by the number of open squares, so that the water ratio is seen by inspection. The advantage of stating the "water ratio" rather than the percentage of water will be seen from the example first quoted where we saw that an increase of 5 per cent. in the percentage of water (90 to 95) means that the relative amount of water is more than doubled, whereas if we reduce the water content from 33 1-3 per cent. to 25 per cent. (water ratio 0.5 reduced to 0.33) the diagram shows that there is little difference in the actual amount of water present in the two cases, although when stated as a percentage the difference seems considerable.

For the wet undrained bog let us take 95 per cent. water (water ratio 19 to 1) as shown by the first column in Fig. 1. The second column which can be called standard peat with 90 per cent. water, represents what may be considered the average condition of a well-drained bog, and the third column with 88 per cent. would hold near the exposed face of a bog where the drainage conditions were exceptionally good. Peat cut by hand and air dried under normal conditions in this country should not contain more than 25 per cent. of water, and that has been taken as the standard for air-dried peat.

It will be seen from the diagram that to produce 1 ton of air-dried peat we must handle 15 tons of raw peat containing 95 per cent. of water, or 7 1-2 tons of 88 per cent. moisture peat. The tons of 90 per cent. moist peat, or 6 1-4 cost of excavating, handling, and spreading a ton or a cubic yard of peat with 95 per cent. water is just as much as that for the same quantity of one with 90 per cent., but in the latter case the yield of finished product is double that in the former. We see, therefore, that between working on a drained and an undrained bog may easily mean the difference between success and failure.

The Calorific Value of Peat

The next diagram, Fig. 2, shows the calorific value of peat containing different percentages of water. On the left we have the number of British thermal units contained in 1 pound of peat, the B.Th.U. being the amount of heat required to raise 1 pound of water 1 deg. Fah. The calorific value of anhydrous peat varies with the percentage of ash and other constituents, but lies between 8,000 and 10,000 B.Th.U. per pound. In the diagram 9,500 B.Th.U. has been taken as an average value for Irish peat. Take the case of a peat with 25 per cent. water. Here 1 pound of the peat fuel contains only 3-4 pound of dry peat, and this can give off 7,125 B.Th.U., but at the same time 1-4 pound

we require 6¼ tons 88% moist peat
" 7½ " 90% "
" 15 " 95% "

FIG. 1—DIAGRAM SHOWING PROPORTION OF WATER IN PEAT.

of water has to be evaporated, which requires 280 B.Th.U., leaving the net calorific value 6,845 B.Th.U. It will be seen from the diagram that with 89 per cent. of water the calorific value of the 11 per cent. of dry peat will be just sufficient to evaporate the 89 per cent. of water and that hence such peat has no net calorific value.

Taking air-dried peat with 25 per cent. water the average net calorific value as fired will be 6,000 to 7,000 B.Th.U., and as coal used for industrial purposes gives from 12,000 to 14,000 B.Th.U. per pound we may take it that 1 ton of coal is the calorific equivalent of 2 tons of air-dried peat.

Fig. 2 also shows the proportion of fixed carbon to volatiles in the various fuels, commencing with anthracite coal and ending in peat, which may be said to be coal in the first stage of formation. In the case of anthracite the carbon runs from 98 to 92 per cent., whereas for peat the fixed carbon is only 25 to 35 per cent.

The ash in Irish peat averages 4 per cent. of the anhydrous peat and is low, judged by American standards, and usually increases from the surface downwards owing to the increased humefication of the vegetable matter which has taken place in the lower layers.

The Elimination of Water From Peat

Part of the water contained in peat is mechanically held and may be removed by pressure, but the remainder appears to be held by the colloidal matter in the peat so firmly that it cannot be removed by even very high pressures. Its complete removal can only be effected by evaporation, but a part of the remaining water may be pressed out after subjecting the peat to some process which alters its structure.

The best way to utilize the calorific energy of the peat, originally the product of the radiant heat of the sun, is to make use of the heat of the sun and its dynamic effects to dry the peat naturally as it is spread on the surface of the bog and not to waste the heat energy of the peat in evaporating the contained water.

When peat, as taken from the bog, is subjected to high and long continued pressure almost three-quarters of the contained water is driven off and the moisture content is reduced from 90 per cent. to 70 per cent., but even in this condition it is still useless for fuel purposes. This represents the maximum effects of pressure on raw heat, and it is now accepted as a fact that peat fuel cannot be prepared by pressure alone.

The drying of peat by artificial heat does not become a practical consideration until the moisture content has reached 70 per cent., and even then it is a very doubtful financial proposition.

Peat has been place in centrifuges, electrical currents, alternating and direct, have been passed through it, freezing has been tried and chemicals been added, and although a certain amount of success has been claimed in laboratory experiments, the economic solution of the problem of artificially dehydrating peat seems to have baffled all.

To get over the objection of leaving the peat in contact with the wet surface of the bog various devices have been employed. In Carinthia poles about 10 feet long are driven into the bog to a depth of 4 feet and transverse spikes driven through the poles, on which the peat blocks are then stuck so that drying is accelerated. Timber trays with wooden laths have also been used and a sample of one is exhibited, but the depreciation and capital charges for such systems are very high.

The Mechanical Winning of Peat

The peat fibres in the bog are arranged

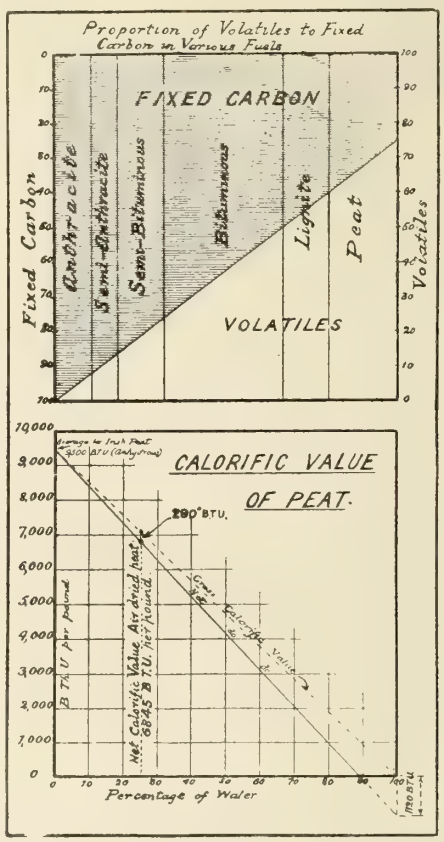

FIG. 3.

more or less in horizontal layers, and for the past sixty years it has been recognized that by macerating and mixing the raw peat the fibres become more uniformly distributed through the mass. This causes a more uniform shrinkage and greater contraction to take place on drying and produces a denser and tougher fuel. Many forms of peat macerating machines have been devised, some of which simply mix the peat to secure uniformity, whilst others attempt the cutting and tearing the fibres. The peat fed into a hopper is pushed through the body of the macerator by a single or double spiral screw. Whilst being forced through the machine the peat is mixed and in some cases forced past rotating and fixed knives of different forms as in the Anrep and Anderson machines.

The peat pulp is then forced through the mouthpiece in the form of one or more streams or bands of peat. Sometimes these bands of peat are received on boards fed over a roller table, the streams of peat being cut into suitable lengths and the boards of peat transported on small wagons from which they are taken and spread on the bog surface to dry. Another method adopted is to run the peat pulp into wagons and transport it to the drying ground, on which it is tipped and levelled to form a layer 5 inches or 6 inches thick.

The present tendency is to concentrate the excavating, macerating, and sod forming and spreading mechanism in one unit. This allows of greater concentration of power units and requires the minimum of supervision and labour.

The dredger excavates the peat from the bog, delivers it into the hopper of the macerator, which in turn forms it into separate pieces. These are automatically placed on a conveyer band which moves out from the macerator as it is gradually loaded, and when completely loaded it automatically tips its contents on to the bog. In this way a strip 100 yards long by 14 inches wide is covered at the same time with the formed peat blocks, and the whole machine then moves forward 14 inches and the next strip of peat is laid down as before. The conveyor girder is supported on mono-rail trucks or on caterpillar tractors.

The peat when spread flat upon the bog is treated just as ordinary "hand cut" peat and subjected to the usual turning, footing, and stacking operations.

Uses of Peat

Attempts have been made from time to time to make paper, building material, alcohol, petrol, and clothes from peat, but the main uses of peat must continue to be for peat moss litter, peat dust for use in the manufacture of cattle feeding, and peat fuel for domestic and industrial purposes, including under the fuel the various distillation products.

The Utilization of Peat for the Production of Power.

When considering the utilization of peat for power production there are two main lines of procedure open to us. The first is to burn the peat and with its fixed carbon and volatiles to complete oxidation in a water-tube or other form of steam boiler and then use the steam thus produced in a turbo-generator for the production of electrical energy. The second alternative is to consume the peat in a gas producer, the peat being partly oxidized with the production from each ton of peat used of some 60,000 to 80,000 cubic feet of a power gas of low calorific value—say, 100 to 150 B.Th.U. per cubic foot—the power gas produced being used in a gas engine or in a gas-

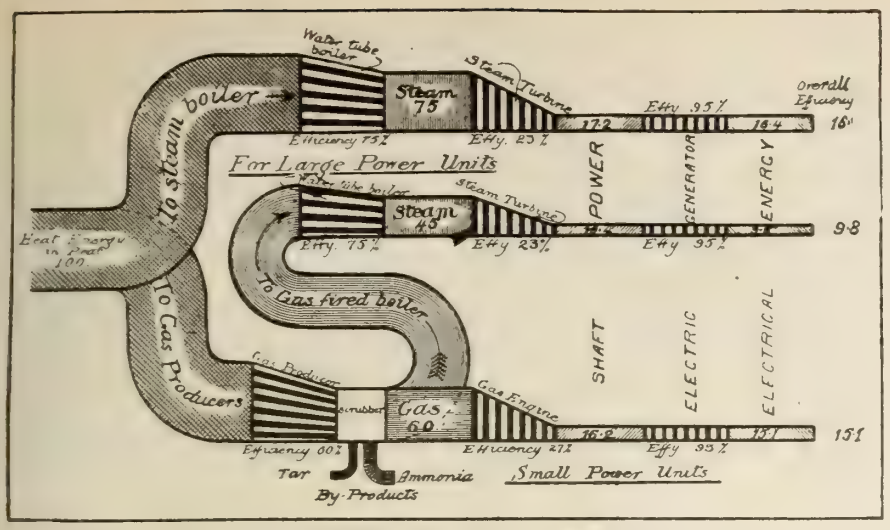

FIG. 3—PRODUCTION OF POWER FROM PEAT.

fired steam boiler and the steam used in a turbo-generator.

Allowable Percentage of Moisture in Peat for Producer Work

Several leading manufacturers of gas producer plants have claimed that they have been successful in using peat containing 60 per cent. to 70 per cent. of moisture, whereas to burn peat in the furnace of a steam boiler the moisture content ought not to exceed 30 per cent. to 35 per cent. Since steam has to be supplied to the producer when using a dry fuel it would naturally be a great advantage if the moisture required could be supplied by the peat, thereby avoiding the necessity of drying the peat to so great an extent.

The diagram Fig. 3 has been prepared to represent the possible ways of utilising the energy in peat fuel. To do this certain efficiencies have been assumed for each stage, at which one form of energy has been converted into another.

Following the upper line in the diagram, about 75 per cent. of the 100 heat units in the peat are available for the production of steam by burning the peat in a water-tube boiler, and these 75 steam units, when used in a modern steam turbine, with a thermal efficiency of 23 per cent., will give 17.25 units of shaft power, which in turn yield 16.4 units as electrical energy. Taking the lower line, the 100 units put through a gas producer with 60 per cent. to 70 per cent. thermal efficiency will give, let us say, 60 units of energy contained in the gas if by-products are recovered. At the same time, certain by-products in the form of tar and ammonia are produced and these may be recovered, the latter as sulphate of ammonia, for which there is wide demand.

Two alternate methods are open to us for the utilisation of the gas. It may be sent by the middle route and burned in a gas-fired boiler, the resulting steam being used in a turbo-generator. A thermal efficiency of 75 per cent. to 80 per cent. with the gas-fired boilers is said to be attainable. but it will be seen that we have one extra step introduced, so that two operations are necessary to convert the heat energy in the peat into steam, as compare to one in the peat-fired steam boiler. This involves further loss of energy, and, in addition, increased capital charges must be borne, so that unless the profits on the by-product recovery plant are of sufficient value this system cannot compete with the direct peat-fired steam boiler. The energy produced by this system equals $100 \times .6 \times .75 \times .23 \times .95 = 9.8$ per cent. of that put in. The method, however, allows large units to be employed, while at the same time by-products are recovered.

The second alternative is to use the power gas from the producer in a gas engine which in turn works a generator. This method offers fairly high efficiencies, but it is doubtful if it can be employed on the large scale, as it is said that serious mechanical difficulties are experienced in the working of large gas engines of 500 horse-power and upwards, and 300 horsepower would appear to be a useful limit. For such powers as 300 horsepower this method gives good results. About 16 per cent. of the heat energy put in appear as shaft power and $(100 \times .6 \times .27 \times .93 = 15.1)$ about 15.1 per cent. as electrical energy. Little can be said about the gas turbine, which would form another alternative. So far it has not proved successful and does not appear to have got beyond the experimental stage.

To arrive at a sound conclusion as to the best method to adopt for the utilisation of the peat we must take into account not only the overall efficiency of the processes involved, but also the labour, depreciation, maintenance, and capital charges. We must further take account of the profits from the by-products when peat is gasified in a producer, and this involves the estimation of the costs of production of the by-products, with the labour, maintenance, capital and amortisation charges on the recovery plant. Even then we are dealing with sulphate of ammonia, a product the price of which has been subject to considerable variation, and one for which, owing to recent developments in connection with the war, it would not be easy to predict a price a couple of years ahead. We must remember that the process of gasification in a producer can be varied within wide limits, and the working of the system and its thermal efficiency depends on the end in view, whether it be the maximum production of by-products or the maximum production of power gas. Both these objects cannot be achieved at the same time, and, in a measure, the failure to recognize this point has led to a good deal of confused thought and rather optimistic forecasts as to the possibilities of by-product recovery plants. The yield of sulphate of ammonia is dependent on the percentage of nitrogen in the peat, and therefore, whereas by-product recovery on one bog might pay, it would prove a failure on another. It will therefore be seen that the problem is a very complex one.

ALCOHOL MOTOR FUEL RESEARCH

Vigorous efforts are being made by British men of science and engineers to discover all the possibilities of alcohol as a motor fuel. The increasing scarcity of petrol, and the prospects that the supplies from all visible resources will gradually shrink until they disappear in twenty-five years or so, lend a special urgency to the problem of finding a cheap and plentiful substitute. Realizing how serious the situation was, the Royal Automobile Club and the Commercial Motor Users' Association, both of Great Britain, united in paying the cost of an ambitious programme of research, at the University of Manchester, into the value of alcohol as fuel. At the request of the Alcohol Motor Fuel Committee, appointed by the British Government to survey the whole question, the programme was put in the hands of Professor Dixon, who recently gave the results of his investigations in a lecture delivered in London. A scientific study was made by Professor Dixon and his assistants of the behaviour of alcohol and of mixtures of alcohol and benzole after ignition. The main object was to find out the conditions which would give the highest efficiency with existing internal combustion engines when run on alcohol or alcohol mixtures. Information of the greatest value to designers has been collected. Investigations in this field have extended to the value of potatoes, beet, maize, and other sources of power alcohol. It is quite possible that many tropical and subtropical plants which have hitherto been regarded as a nuisance or as of little value will prove to have a high yield of the substances out of which, by fermentation, alcohol may be produced in large quantities at a low price. The research now being conducted may therefore be the means of transforming the economic prospects of more than one country.

The Advantages of Superheated Steam

A General Discussion of the Properties of Superheated Steam, and Its Uses in Both Turbine and Reciprocating Engine Practice—A Comparative Test on a Recent Installation is Given.

BECAUSE fuel used for power plant or power station service represents the largest single item in the cost of producing power, its utility must be increased. Each pound of coal burned, each gallon of oil consumed under a boiler for the generation of steam not only must be accounted for, but also must be made to do more useful work.

Of all the means known or practiced to improve the efficiency of a plant, the application of high degrees of superheat, for the investment, shows the most profitable and practical returns. Because superheat offers economies greater than any other single improvement in power plant design, it commends itself to even closer consideration than engineers have hitherto given it.

The returns from superheating are evidenced by a considerable reduction in the cost of operating a steam plant. Within practical limits of temperature, it has been found that the higher the superheat, the greater the economy.

The increased economy is effected in general in four ways, viz.: by increasing boiler efficiency, by reducing condensation losses in steam lines, by reducing the steam consumption of the prime mover, and by increasing the capacity of the plant.

Superheating Increases the Boiler Efficiency

A definite amount of heat is required to superheat steam to a certain temperature and this heat is furnished by the fuel. When a definite weight of steam is generated, additional fuel will be consumed to superheat this steam.

Let us assume a boiler designed without a superheater to give the highest practical thermal efficiency. Suppose we install a properly-designed superheater in this boiler. It will be found that the overall thermal efficiency of the combined boiler and superheater will be greater than the boiler without the superheater when evaporating the same amount of water, because, by the addition of the superheating surface more heat is absorbed and the final uptake gas temperature is lowered. This result can be accomplished, however, only when the superheater is correctly designed so as not to obstruct unduly the flow of the gases through the boiler. Undue obstruction to the gases would decrease the overload capacity of the boiler. A properly designed superheater will not alter furnace conditions in any way. Considering a given furnace condition and a given rate of firing, these facts are indications of added efficiency.

Eliminating Steam Line Condensation

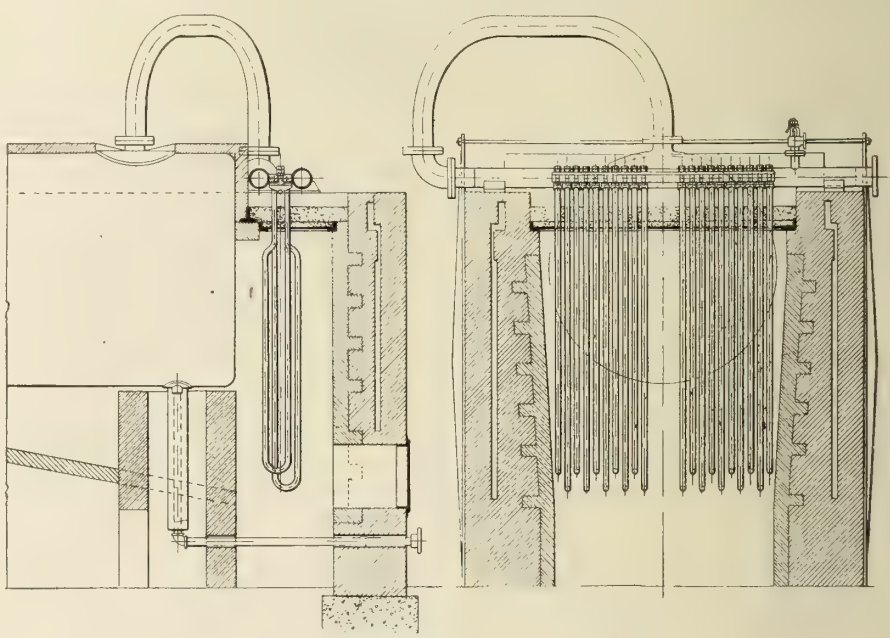
Many power plant installations are forced by local conditions to operate their prime movers at long distances from the boilers supplying the steam. The long pipe lines carrying the steam often are run out of doors where they are exposed to all kinds of weather. These conditions naturally have a marked effect on the quality of steam when it reaches the point where it is to be used.

Superheated steam prevents condensation in steam lines and delivers dry or superheated steam within practical limits to the steam user. This advantage is due to the fact that no moisture or water is carried over from the superheater and also because the low thermal conductivity of the superheated steam prevents condensation. Superheating is advantageous not only from an economical standpoint, but also because it eliminates water hammer and its attendant engine and pipe troubles.

It is a matter of historical interest that the first recorded use of superheated steam was necessitated by the condensation which took place in a long steam line.

Long pipe lines now carrying saturated steam can be used for superheated steam without any change, resulting in a great saving in the available heat and quantity of steam delivered for power purposes. This fact alone should make the use of superheated steam on long pipe lines universal practice.

When condensation in steam lines is reduced, both steam and coal are saved, because in the generation of steam, about nine-tenths of the heat absorbed by the water in evaporating it and raising the steam pressure is latent heat. When steam is condensed, latent heat is liberated and unless it performs useful work it is wasted. Condensation, therefore, occurring in pipe lines, represents an absolute waste of nine-tenths of the heat, and if the condensate is not returned to the boiler all the heat is wasted. A superheater is absolutely essential to raise the temperature of the steam to a point that all of it may be transmitted to its destination and used without condensation losses.



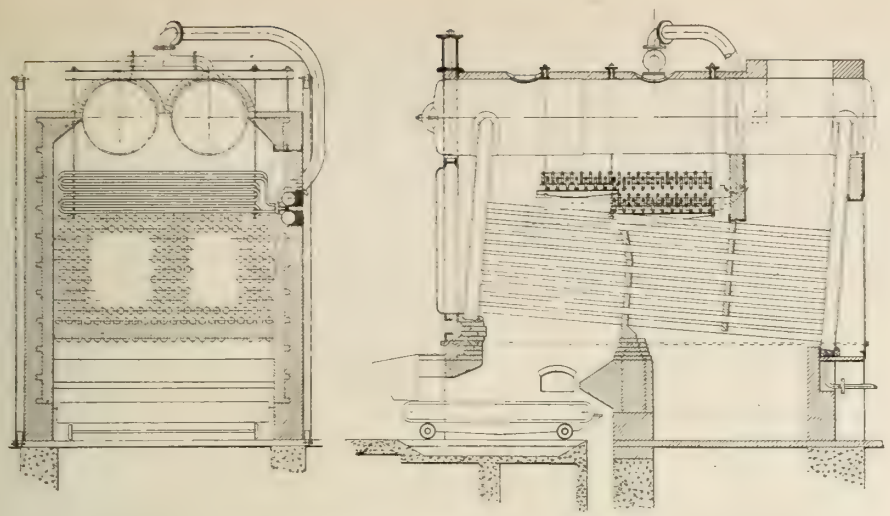
TYPICAL ARRANGEMENT FOR H. R. T. BOILER.

Importance of Superheat in Steam Turbines

High degree superheat is of vital importance in steam turbines, and the steam turbine is particularly adapted to its use. All turbine plants of any size are now using superheat, several modern plants operating at superheat temperature up to 250 deg. Turbine manufactures have made a strong claim in favor of turbines, in that high degrees of superheat can be used. The most economical steam prime movers of to-day realize steam with as high as 300 deg. superheat. These turbines produce a K.W.H. for 11.5 pounds of steam or a brake horsepower hour for 8 pounds of steam.

The water rate of an economical steam turbine will be reduced 1 per cent. for every twelve degrees of superheat up to 200 deg. This figure is based on large and economical turbines. Small turbines, inherently less economical, show a greater proportionate saving with superheated steam.

The above results are based upon the assumption that perfectly dry steam has been delivered to the superheater. This condition, however, seldom exists. The usual type of horizontal return tubular



TYPICAL ARRANGEMENT FOR HORIZONTAL WATER TUBE BOILERS.

boiler with a comparatively large water and steam capacity delivers wet steam. The modern water tube boiler with less water and steam space is much worse. This condition is accentuated, particularly by the fact that the modern water-tube boiler is forced to evaporate water at a rate of 3 or 4 times that of the return tubular boiler, and the percentage of moisture in the steam from such a boiler is high. Take for example a 500 h.p. water tube boiler having a 42 in. diameter steam drum. At normal rating such a boiler will deliver 15,000 lbs. of steam per hour. Conditions often arise when such a boiler will be called upon to evaporate 30,000 to 40,000 lbs. of water per hour. Superheat takes out all the moisture that otherwise would be carried over, and is, therefore, particularly beneficial when boilers operate at high capacities.

It is this moisture which is particularly damaging to steam turbines. It reduces the efficiency by the excessive friction between the water and turbine parts. One authority points out that a turbine without superheat is merely a form of water brake, for every ounce of water passing through, no matter how finely divided, is inert material, and serves to check the running of the machine.

The internal surfaces of the turbines are enormously increased beyond those in reciprocating engines, and the effect of temperature range in augmenting condensation is very great, even though the temperature in the turbine does not change so widely.

The destructive effect of water and moisture on the turbine blading is too well known to be more than mentioned. The erosion of turbine blades due to water is very rapid. The effect of this erosion is immediately felt in increased steam consumption. When highly superheated steam is used, however, water is not present to cause this erosion. Blade wear is greatly reduced through superheating and reblading is necessary only after much longer periods of operation than when saturated steam is used.

Superheating Increases the Efficiency of Reciprocating Engines

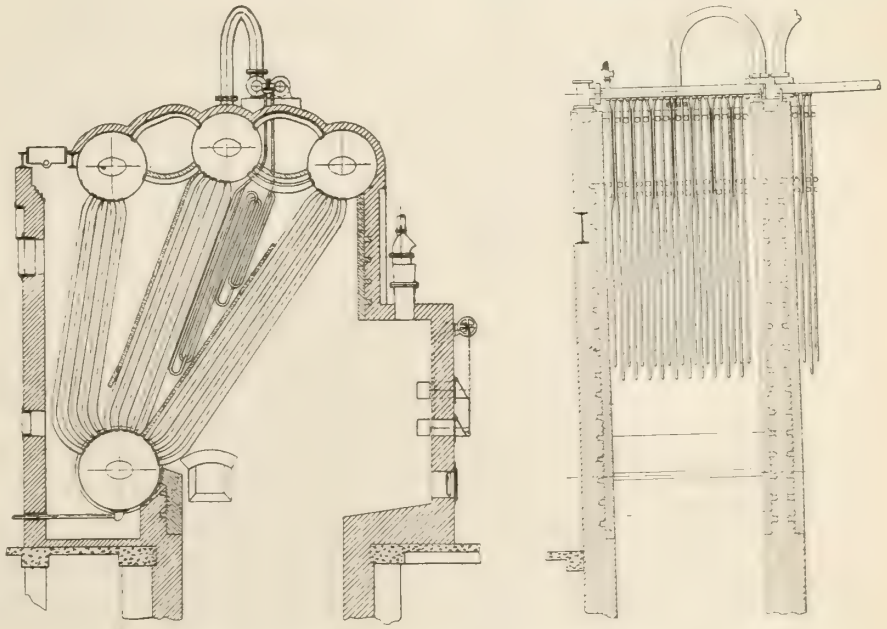
Generally speaking the reciprocating engine will be benefited more by superheat than the steam turbine will. The saving to be expected by superheating is dependent on the amount of cylinder condensation that would occur in the same engine if no superheat were used. Evidently, the greater this condensation, the larger is the saving possible.

When steam is superheated 200 deg. or even 250 deg. Fahr., it can be exposed to the cooling action of the steam chest and cylinder walls without condensation, and has 30 to 40 per cent. greater specific volume than saturated steam of the same pressure. For example, 1 lb. of water at 170 lb. pressure absolute produces 2.68 ft. of saturated steam at 368 deg. Fahr. temperature. After passing through the superheater and gaining 200 deg. superheat, the volume will have been increased to 3.54 cu. ft. A part of this increased specific volume is lost before the expansion of the steam in the cylinder takes place on account of the cooling action of the cylinder head, piston and cylinder walls. While the superheat in the steam entering the cylinder may be 200 deg. to 250 deg., the superheat of the steam in the cylinder at the moment of cut-off is considerably less. The elimination of all condensation losses together with the increased volume of the steam, effects substantial savings in the steam consumption and in the fuel consumption when compared with saturated steam operation under the same conditions.

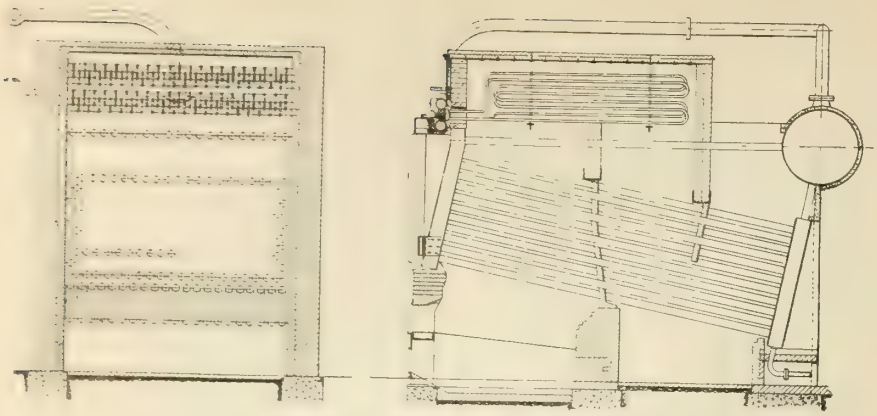
The opinion frequently has been advanced that the mean effective pressure in cylinders using superheated steam is altered from that existing when saturated steam is used, the initial pressure, the point of cut-off and piston speed, of course, being assumed as the same in each case. Theoretical considerations would indicate that a lower mean effective pressure with superheated steam is obtained, and this conclusion would be based upon the knowledge that the expansion curve of superheated steam is steeper, that is to say falls more rapidly than with saturated steam. In practice, however, with highly superheated steam a mean effective pressure at least equal to that with saturated steam is obtained. An explanation will make this point clear. For example: in simple non-condensing engines the back pressure line of an indicator card is decidedly lower with superheated steam than with saturated steam, a condition to be expected because the steam exhausted contains less moisture. It is, therefore, lighter than saturated steam, and flows through the exhaust passages with less resistance. Mr. C. D. Young, before the American Society of Mechanical Engineers, in December, 1912, gave conclusive evidence of this fact.

In the case of multi-expansion reciprocating engines the cards taken from the low pressure, and, in the case of triple engines, from the intermediate pressure cylinder, show that a higher m. e. p. is obtained with superheated steam. In the high pressure cylinder of multi-expansion engines it is generally true that the cut-off should be increased if the power output of the engine is to be maintained.

But our consideration of the possi-



SUPERHEATER ADAPTED TO STIRLING TYPE.



TYPICAL ARRANGEMENT FOR CROSS DRUM TYPE.

bility of increased engine power, due to superheating, must not stop here. Consider a saturated steam plant in which the boilers are operating at their full capacity to supply the steam demanded by the prime movers. Take this same plant and superheat it—the decrease in steam consumption per horsepower hour will result in a reserve boiler capacity which will make possible either the operation of the boilers at lower rating or will furnish the additional steam necessary to meet an overload on the prime mover. In other words, superheating makes it possible to increase the power which the prime mover may develop over what it could produce with saturated steam.

In new installations, the use of superheated steam permits the use of engines having larger cylinder diameters and enables them to be operated with shorter cut-offs. Because cylinder condensation is eliminated, the gain in economy due to a more effective expansion of the steam is realized.

Experiments have shown that the degree of superheat necessary to prevent cylinder condensation varies as a general rule with the ratio of expansion. In American practice the steam temperatures ordinarily recommended are: up to 500 deg. Fahr. for Corliss and slide valves; up to 650 deg. Fahr. to 700 deg. Fahr. for piston and poppet valves.

The gain from decreased steam consumption due to superheated steam is ordinarily expressed in per cent. This gain will vary in various types of engines with the different superheat temperatures used. For example, with 150 deg. superheat, the following gains are produced: in simple engines 22 to 24 per cent.; compound engines 16 to 19 per cent.; triple expansion engines 14 to 16 per cent.; uniflow engines 10 to 12 per cent. It is, however, an assured fact, and a strong argument for the more general adoption of high degree superheat, that only engines designed for high degrees of superheat and using it can successfully compete in economy in the power generation field.

Advantages When Operating at Reduced Pressures

It is often necessary, particularly with old boilers, to reduce the operating pressure. This condition results in a loss in plant capacity. Superheating such boilers will enable them to meet the power demands of the plant at the reduced pressure just as well as the boilers did before the pressure was reduced. Furthermore, superheating in the majority of cases will provide an additional reserve power over that of the plant before the pressure was reduced.

Power Plant Cost With Superheat

The installation of superheaters materially lowers the plant cost. Where it is used, a smaller amount of boiler horsepower is needed to deliver the same power. Roughly speaking, six boilers equipped with superheaters, furnishing 150 deg. of superheat, will carry the same power load as seven boilers delivering saturated steam. By reason of this fact alone, smaller feed pumps, smaller stacks, smaller coal handling apparatus and less coal storage space are sufficient for the demands.

Piping can be reduced in size because higher steam velocities with superheated steam are possible. This reduction in pipe size will effect a saving not only in the pipe line but also in valves, fittings and covering.

In the turbine room, superheated steam will allow the use of a condenser of smaller size than if saturated steam were used. Consequently, smaller circulating water pumps, hot well and vacuum pumps can be used and minor apparatus such as steam separators often can be dispensed with.

These items materially reduce the initial plant cost.

Conclusion

When superheating is correctly applied to the individual conditions in a specific plant, it is the one means which will positively show an improvement in power plant operation in at least one and probably all parts of the plant where steam is used.

The following test was recently carried out at the Conneaut, Ohio, shop power plant of the "Nickel Plate" R.R. The plant contains the following equipment—Boilers (3) 180 horsepower H.R.T. boilers; furnaces: hand-fired; fuel: coal and sawdust; engines: 1 150 h.p. Corliss, 1 175 kw. direct-connected high-speed engine, 1 75 h.p. balanced valve engine; air compressor: 1 1,050 cubic feet capacity, slide valves on steam end; pumps; duplex; steam hammers: 1 1,200-lb, 1 2,000-lb. All these units are now operated on superheated steam, and some of them are several hundred feet from the boiler room.

Development of Long Distance Transmission

In This Lecture Delivered Before the Johns Hopkins University as One of the John Aldred Lectures the Progress of Electrical Development is Reviewed from 1876 to Date.

By PAUL M. LINCOLN, Consulting Engineer, Cleveland

(Continued from last issue.)

THE fact that power could be brought into these mines by electrical means opened up a tremendously large field for electric transmission of power, and this industry immediately took hold of the West and developed rapidly. Mr. P. N. Munn gives a very interesting history of the development of the Telluride Power Company and the other companies which sprang from this development in Cassiers' magazine for January, 1905. Those interested will find a complete account of this development in that magazine.

The most interesting feature of this development, historically speaking, is that pointed out above, namely, that single phase alternating current was used, and not the polyphase alternating current, which would be the only thing considered under similar conditions to-day.

The use of the single phase system by this Colorado gold mine brought strongly to the attention of the engineers of the time the necessity of developing an alternating current system of generating and transmission and distribution, which should better take care of the needs of the time. Development work was, therefore, pushed by the Westinghouse Company on the polyphase alternating current system of generating and distributing, which had a beginning about two years previously. While most of the demand was for single phase power used for lighting only, the demand for power for the purpose of driving machinery began to be recognized as a very important future development for alternating current, and all possible energy was directed at improving the methods of generating, transmitting and distributing polyphase alternating current power.

During the summer of 1891 an experiment in power transmission of rather extensive character occurred in Germany, which had an important influence upon the development of power generation and distribution by alternating current. This was the so-called Frankfort-Lauffen transmission. There were three unique features of this Frankfort-Lauffen transmission. The first was that the voltage used was higher than anything that had previously been attempted, namely, 30,000 volts. The second was that the distance of transmission was longer than anything heretofore attempted, being about 30 miles. The third unique feature was that polyphase was used and not the single phase, which had been used universally in all commercial enterprises before that time. This transmission was admittedly an experiment, undertaken mainly for the advertising value it had in connection with an exposition which was going on during that summer in the City of Frankfort. There is a water power of some considerable size at Lauffen, and this alternating current transmission was undertaken for the purpose of bringing the water power from Lauffen to Frankfort, the power being used largely for illumination. However, the fact that this transmission was carried on successfully had a very marked influence upon the development of the art of transmission and distribution of electrical energy. It gave electrical engineers great confidence in some features of this method of transmission, in which, before that time, there was not much confidence. The fact that a voltage as high as 30,000 volts could be carried successfully and that power could be successfully transmitted over distances up as high as 30 miles gave electrical engineers of that time great hope that the alternating current polyphase method of transmission had a great future before it.

It was at about this period that a group of New York financiers decided to undertake the development of power at Niagara Falls on a scale that exceeded anything attempted up to that time. The question immediately arose as to how this power should be generated, transmitted and distributed. An International Commission of Engineers was appointed by these financiers for the purpose of advising upon this question. This commission was composed of some of the best known scientists and engineers of the day. Dr. Coleman Sellers, of Philadelphia, served as chairman. Dr. Sellers was recognized as one of the foremost mechanical engineers of his day. Undoubtedly the best known member of this commission was Lord Kelvin, the well known English scientist. Two other members were Professor Wm. C. Unwin, a well known English mechanical and hydraulic engineer, and Colonel Turretini, a Swiss hydraulic engineer. It is significant to note that the electrical profession was not represented by a single member on this commission. It is also significant to note that it was by no means a foregone conclusion that the electrical method of generation and distribution would be adopted by this commission. If a similar commission should be appointed to-day to pass upon a similar question the electrical method would be the only one which would have the slightest consideration, but in those days the electrical method was still on trial, and it by no means had the call when so large and important a problem as transmitting an amount of power which was expected to reach from 50 to 100,000 h.p. was to be developed and distributed. A fact which is of interest to Baltimoreans is that Professor Henry Rowland, at that time Professor of Physics in the John Hopkins University, appeared before this commission in the capacity of an expert and was one of the advocates of the electrical method of generating and distributing power, and he also advocated that the method adopted be the alternating current polyphase method.

The upshot of the deliberations of this commission was that during the year 1893 the alternating current two-phase system was chosen for the purpose of developing and distributing Niagara power. The engineering advice rendered by the Westinghouse Electric and Manufacturing Company was one of the important factors in arriving at this decision. The engineering advice from that source was followed in almost every particular in the decisions arrived at by this commission. One of the points, however, where the decision of the commission differed from the advice given them by the Westinghouse engineers was in the matter of frequency. A short history of the matter of frequency up to that time may be of interest.

The frequencies first used with alternating current were comparatively high, being 133 cycles per second as the standard chosen by the Westinghouse Electric and Manufacturing Company, and 125 cycles per second by the Thomson-Houston Company and other competitors that entered that field after the Westinghouse Company had demonstrated the successful application of alternating currents to electric lighting. These frequencies were standard for a number of years after the beginning of the alternating current method of generating and distributing electricity for lighting purposes. As soon as it became evident that the alternating current would have to enter the power field, as well as the lighting field, it became recognized that a lower frequency would be desirable. After some consideration a frequency of 60 cycles per second was selected by the engineers of the Westinghouse Company, and about the year 1890 equipment for the lower frequency of 60 cycles began to make its appearance upon the market. When the decision to use alternating current polyphase system for the Niagara development was finally made by the commission the engineers of the Westinghouse Company recommended that this frequency of 60 cycles per second, then a comparatively new thing, be used for the Niagara development. Objection to so high a frequency was made by some of the advisers of the Niagara commission, not-

ably Professor George Forbes, a well known English electrical engineer, who advocated the adoption of 16 2-3 cycles per second, and even suggested going to one-half of this value, namely, 8 1-3 cycles per second. On the other hand, as indicated above, the engineers of the Westinghouse Company advocated 60 cycles per second. The question was finally solved by the directors of the Niagara Falls Power Company adopting a compromise between these two frequencies, namely, 25 cycles per second. A factor which entered into this decision was that the speed of the water wheel had already been chosen at the time that the frequency was made—250 revolutions per minute — and the frequency selected must, of course, correspond with the water wheel and generator speed. I think I am safe in stating that if this decision were to be made again to-day, in the light of all of the knowledge which we have gained in the last 25 years, the advice given by the Westinghouse engineers at that time would be followed and a frequency of 60 cycles rather than 25 adopted for this important development. However, there were reasons which seemed thoroughly convincing to the commission at that time for making the decision which they did; the main reason was that this was a power plant, not a lighting plant, and that the frequency selected should be one suitable for power transmission and power development rather than for lighting purposes. The decision to use two-phase rather than three-phase for this development followed from the consideration that a large amount of the energy would be used in single-phase furnaces and for other single-phase purposes. The consideration that it was easier to divide single-phase load among two phases rather than among three led to the adoption of the two-phase system instead of the three-phase system.

This decision in the year 1893 to use the alternating current polyphase system for the purpose of generating and distributing the Niagara power was followed shortly by an order given to the Westinghouse Electric and Manufacturing Company for three 5,000 h.p. alternating current generators, together with some of the other necessary equipment to go with them. It is interesting to note that these generators, at the time they were designed and built, had a capacity of more than four times the capacity of the largest previous alternating current generators. A capacity of 5,000 h.p. for an alternating current generator does not seem large to-day, but at that time it was far beyond anything which had been built before, and as a consequence many new problems entered into the design of these generators. The engineers of the Westinghouse Company are, in my opinion, due for a very great amount of credit for the manner in which the work was carried out. The use of an "all mica insulation" in the armature of these generators is one of the unique features adopted in that design, and is one of the things which has lasted to this day.

Commercial operation of the Niagara Falls Power Company in distributing power to its customers began on August 26th, 1895, and it is interesting to note that at least one of the original generators still runs after a lapse of nearly 25 years, with exactly the same armature windings as it started with on August 26th, 1895. The fact that mica insulations were used on these generators is unquestionably responsible, to a very large degree, for this long period of uninterrupted service. During the following summer a transmission line between Niagara Falls and Buffalo was built, and operation on this was started during the summer of 1896. The distance of transmission on this transmission line is 22 miles, and the voltage first used was 11,000 volts, three-phase. While this was not excessive either in point of distance or in point of voltage in one this transmission exceeded anything that had been put into operation before, and that is in the amount of power which was transmitted over it. This feature introduced some new problems, and a great many of these new problems introduced by the increase in the amount of power were met for the first time in that particular transmission.

The problem of circuit interruption was met in aggravated form in that transmission. Up to the time of this transmission it had been customary to use fuses as the only protection on transmission lines, and they had served very satisfactorily. However, in the case of the Niagara-Buffalo transmission line the amount of power was so large that fuses did not give satisfactory operation, and it was recognized there for the first time that something other than fuses would have to be developed in order to get proper protection from overloads, short circuits, etc. To meet this condition the oil switch was suggested and developed, the first step in this important development being taken by the General Electric Company of Schenectady. This, however, was only one of the many new problems that were met with for the first time in this installation, and in the solution of which the engineers of that enterprise were vitally interested.

The Niagara plant was the pioneer central power plant of this country, and its success in both a financial and engineering sense gave a great impetus to the development of power transmission and distribution, particularly by the alternating current method. While this Niagara system was one of the first, and one of the largest, it was by no means the last of such systems to be installed. They began to appear in all parts of the country, and the use of transmitted power began to assume a very important place in the industrial life of the country. Growth and development in all phases of the alternating current method of transmitting and distributing power were the order of the day. It may be interesting to trace first a brief history of the development that has taken place in the matter of the voltage of transmission.

REMARKABLE DROP IN OUTPUT OF CENTRIFUGAL PUMPS AFTER STARTING

Observations made by the author indicate that many centrifugal pumps show a gradual falling-off in efficiency after running for some time. Two characteristic cases are cited in connection with the large pumps used for pumping the Haarlem mere. In the first the output fell to 30 per cent. below the normal, and in the second case a marked increase in the energy consumption was noticeable shortly after the pump was started. On stopping and restarting the pump, the normal output and energy consumption were again obtained; but the conditions gradually fell back to those previously observed. After discussing the influence of a possible accumulation of gas (from the peaty soil) in the suction pipe, the author rejects this explanation as being insufficient. He ascribes the cause to the fact that turbine pumps of the Francis type are designed on the assumption that the inflowing water is moving in an axial and not a rotary direction. This assumption is undoubtedly correct during starting, but it can be readily demonstrated that very little would be required to impart a rotary movement to the incoming water column—i.e., the mass of water would move in a spiral through the pipe. This rotary effect would explain the phenomenon and also the fact that in turbine pumps with a high circumferential speed, and where little or no rotary motion would be imparted to the incoming column of water, this falling-off in output disappears. The author is of opinion that the transmission of this rotary motion from the rotor of the pump back along the incoming water column is considerably accelerated by the presence of large quantities of suspended matter in the water. The obvious solution of the difficulty for low-speed turbine pumps would be the introduction of a rib or ribs in the suction pipe, to prevent a rotary motion from being imparted to the incoming water column.—J. C. Dijxhoorn ("De Ing.").

"THE PETROLEUM OUTLOOK"

What should prove of great interest to all persons genuinely concerned in fuel problems, is a monograph published by Arthur D. Little Inc., of 30 Charles River Road, Cambridge, Mass., and entitled "The Petroleum Outlook." The work discusses in plain language the status of all the oil fields and their present development, with future prospects. Several charts and a large map are included, showing the entire resources of the United States. The subject matter is highly interesting and gives food for thought. The monograph will be supplied free to those interested on application.

The Theory and Practice of Electricity

In These Articles the Theory Will be Developed Sufficiently to Enable the Practical Man to Grasp the Underlying Principles of Apparatus Under His Care, Both Direct Current and Alternating

W. F. SUTHERLAND

AS an aid to the better understanding of the principle underlying the action of the dynamo and motor, Fig. 1 is given. A conductor is shown passing between the poles of a magnet and assuming first the case of a motor current is assumed to be flowing through it in the direction given by the large arrow. Remembering what has been said about the magnetic flux surrounding a wire and its direction in space, the small arrow running in a circular direction around the wire will represent the magnetic flux surrounding it. Arrows are also shown travelling from one pole of the magnet to the opposite one. These represent the magnetic flux due to the magnet itself. Observe the directions of these two fluxes above the wire. One will be seen to oppose the other. On the other hand the directions of the two fluxes below the wire will be seen to be the same. The resulting action may be considered to be as follows:—

When the two fluxes oppose each other the one counteracts the other and the number of lines of force is lessened. On the other hand where they are in the same direction the field will be strengthened. It will be as if the magnetic lines of force proceeding from the north pole of the magnet finding the path above the wire difficult slide around the wire on the under side even though the path be slightly longer. Since the path is longer they will, however, tend to straighten out and in doing so will exert a force upon the wire tending to push it upwards. The action corresponds to that which would take place if the lines of magnetic force consisted of bands of elastic stretched into exactly the same shape. A force due to the interaction of the conductor magnetism and that due to the magnet pole faces then results which for this particular instance acts upwards. In the motor the conductor moving upwards, as it is supposed to be free and not rigidly held down, continually cuts lines of force or may be said to pick them up from in front of itself and crowd them in behind.

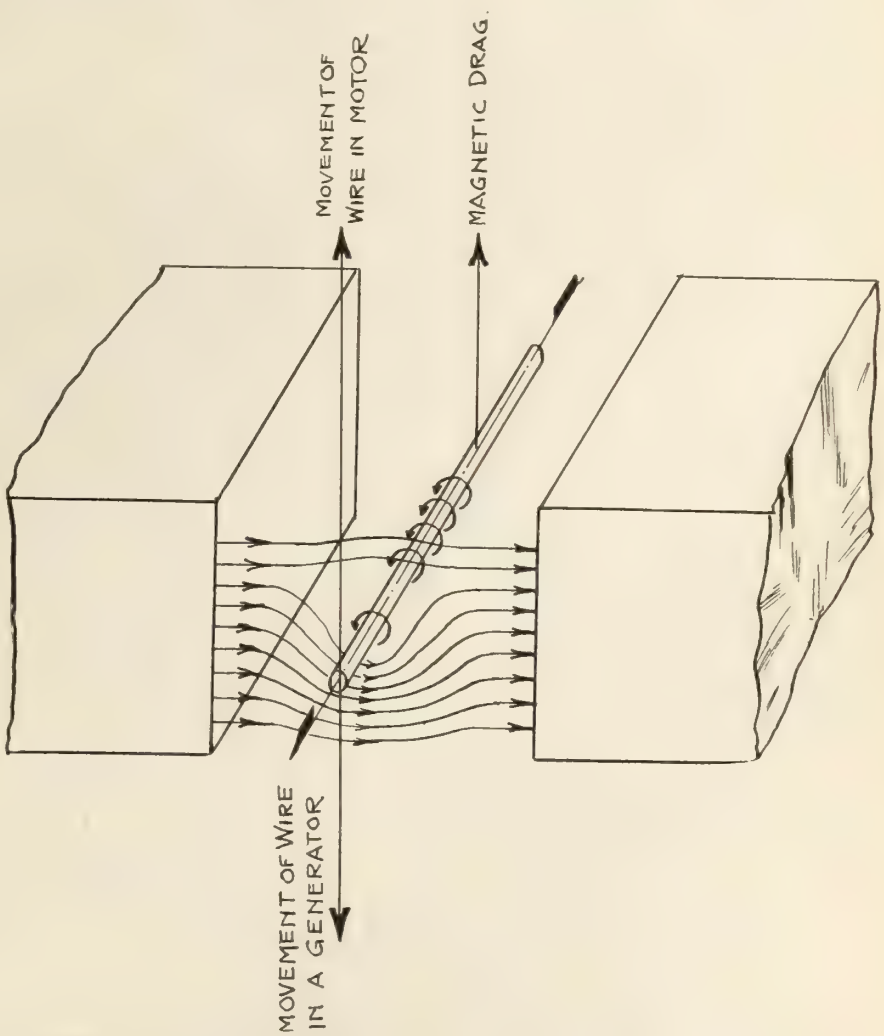
In the dynamo the action may be represented by the same diagram. Only in this case the conductor is pushed by mechanical force in a direction opposite to that which it would take if left free to move as in the motor. The magnetic force still exists but in this case is weaker than the force tending to move the wire between the pole faces. It is just as though a wire were pushed across a number of stretched elastic bands. The cutting of the lines of force by the conductor in this case generates the current of electricity. In other words in the motor the directions of the tendency to move and the actual movement are the same, while in the dynamo they are opposite and the magnetic force or drag may be spoken of as the resisting force which absorbs the work done in rotating the armature.

In the dynamo not only does the direction of the generated e.m.f. depend upon the directions of the magnetic flux and the motion but its strength varies as the speed with which the conductor moves and with the strength of the magnetic field. That is to say, if the speed with which the conductor moves were doubled, the voltage generated would also be doubled and if the flux were doubled while the speed remains constant the voltage would also be increased to the same extent. If the speed and voltage were both doubled the voltage would be quadrupled.

Three quantities are involved in the elementary dynamo or motor, the direction of magnetic flux, the direction of the electro-motive-force in the wire and finally the direction in which the wire moves. The action in the case of the motor, as explained above is not the same as in the dynamo and for the easy remembering of the relations for both cases two simple rules are given.

In the case of the **dynamo** the **right** hand is used and if the forefinger be taken as representing the lines of force, and the thumb as representing the direction in which the conductor is moved, then the middle finger shown pointing downwards will represent the direction in which current will flow.

In the case of the **motor** the **left** hand is used, the thumb, first finger and



MAGNETIC FORCE AND ACTION OF CONDUCTOR IN A MOTOR AND DYNAMO.

middle one representing the same quantities; the left hand is shown in Fig. 3 with the forefinger pointing in the direction of the magnetic flux and the

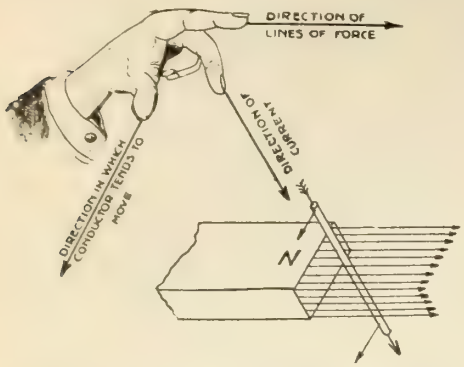


FIG. 2—RIGHT HAND RULE FOR REMEMBERING FLUX CURRENT AND MOVEMENT OF CONDUCTOR RELATIONS FOR THE DYNAMO.

middle finger pointing in the direction in which the current flows. The thumb indicates the direction in which the conductor will move under these conditions.

The Commutator

In actual practice an armature never consists of a single wire as shown in Fig. 1 but at the very least would contain two in the form of a loop as shown in Fig. 4. Let us suppose Fig. 4 is an elementary armature of a generator and suppose it to be moving in the direction indicated by the arrow. The left hand turn moving downwards and cutting

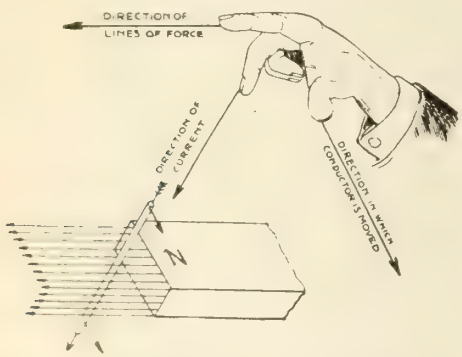

FIG. 3—LEFT HAND RULE FOR REMEMBERING FLUX CURRENT AND MOVEMENT OF CONDUCTOR RELATIONS FOR THE MOTOR.

magnetic flux will have an electro-motive-force induced in it causing current to flow towards the observer and out through the left hand brush. The right hand wire moving upwards at the same instant has an electro-motive-force induced in it in the opposite direction or away from the observer. Travelling in this direction this electro-motive-force will cause current to flow around the wire at the rear and down the left hand side of the loop to the left hand brush the same as before, the two conductors thus reinforcing each other and if the circuit exterior to the generator be closed causing a flow of current out the left hand brush through the exterior circuit and back through the right hand one. When the wires, due to their rotation reach a point at right angles to that shown or when they are in a vertical position no voltage is generated and no current flows. In this position the brushes are touching both sectors on the commutator if they be wide enough. Immediately after this position is reached the conductor which formerly was on the right hand side and was moving upwards, begins to move downwards on the left hand side and its end connected to the commutator is put into communication with the left hand brush. Since in moving downwards the electro-motive-force generated is towards the observer as before a continuous flow of current is set up.

The brushes by rubbing on the commutator thus not only form a path for the current to flow to and from the armature but serve also to give a continuous or uni-directional current.

If instead of a split commutator two rings had been installed one to each

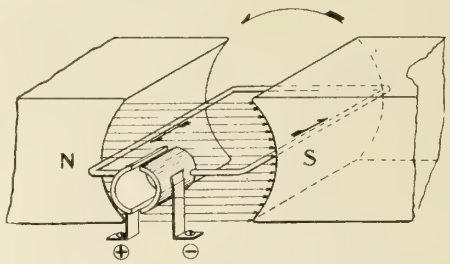

FIG. 4—SIMPLE ARMATURE WITH ONE COIL.

end of the coil, an alternating current would be delivered, for each side of the loop would have a current flowing in it first one way and then the other as it came under the influence of first one pole and then the other.

If two coils of wire similar to the one described be mounted on an axis at right angles to each other with the four terminals of each coil connected to a four

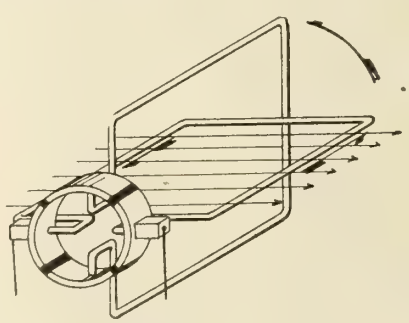

FIG. 5 -TWO-COIL ARMATURE.

part commutator as shown in Fig. 9 then the electro-motive-force generated would be more nearly uniform and in practice commercial machines having a large number of coils give an almost uniform flow of current and in the case of motors give a uniform turning movement or torque.

NEW PUBLICATIONS

The Armstrong Cork Company, Pittsburgh, have issued a new publication, "Nonpareil Insulating Brick," a 72-page book on the insulation of high temperature industrial equipment, such as boilers, furnaces, stills, hot blast stoves, ovens, kilns, etc.

While dealing particularly with the description of Nonpareil Brick and their uses, the book is more than a catalogue. The subject of heat insulation has been thoroughly studied from both the theoretical and practical standpoints, and the results here compiled contribute to make this book a really valuable and instructive treatise. It is conveniently divided into sections, each dealing with a particular type of industrial apparatus so that any one can readily find the data for the equipment in which he is especially interested. Operating records, with and without insulation, are given, actual dollars-and-cents savings demonstrated, and the economy and advantages to be secured by the use of Nonpareil Brick described in a most interesting and convincing manner.

The book is attractively and substantially bound and profusely illustrated. Its subject matter is of such vital importance to all industries employing high temperature equipment, that plant managers, superintendents and engineers will find it a valuable addition to the technical library.

COAL RESEARCH

The economical use of coal is a problem which concerns engineers in all parts of the world. It is especially interesting in connection with the "carbonisation" of coal at temperatures in order to obtain smokeless fuel, gas, oil and numerous valuable by-products. This problem involves a close scientific study of exactly what happens to different kinds of coal at various temperatures. Mr. Sinkinson of the Imperial College of Science, London, has hit upon a most ingenious method of discovering at what temperature coal begins to change into coke. He makes use of the fact that coke conducts electricity, while coal does not. By measuring the electrical resistance of a sample of coal as it is gradually heated he has fixed the temperatures at which various coals enter into the critical stage at which they give off their valuable products.

The Arthur S. Leitch Co., 1,002 Kent Building, Toronto, have recently taken over the agency for the Brown Instrument Company, of Philadelphia, and will handle their complete line of thermometers, recording pressure gauges, pyrometers, draft gauges, and recording tachometers. This will add greatly to the convenience of users of these instruments in Ontario, and should be of interest to those interested in this class of equipment.

Steam Engine Development in the Maritimes

An Interesting Account of the Growth and Development of Engineering Practice in the Lower Provinces—Read Before the Enginering Institute of Canada.

By D. W. ROBB, M.E.I.C.

ALTHOUGH Nova Scotia, New Brunswick and Prince Edward Island, the Maritime Provinces of Canada, are more widely known for the extent and importance of their fisheries, lumbering, mining and some departments of agriculture, particularly apples, potatoes, etc., than for mechanical and engineering achievement, it is interesting to find that in the early development of steam engines for steamers, locomotives, and later in connection with electrical apparatus, a department of engineering which has contributed more towards the rapid progress of the world during the nineteenth century than any other; the little provinces by the sea were among the first on this side of the Atlantic.

When we remember that the first practical steam engines were built by Watt from 1775 to 1800, and that we are only now celebrating the centenary of Stephenson who started the steam locomotive on its triumphant career, it may surprise many of us to find that as early as the years 1844-48 and 1854, John Waring and John Smith, pioneer engineers of St. John, N.B., designed and built marine engines for steamers running on the St. John River. Stationary engines were built by Fleming & Humbert at St. John, N.B., as early as 1838, and locomotives were built by Mr. Fleming before 1860. One of Mr. Fleming's locomotives hauled a train for the late King Edward, then Prince of Wales, when he visited Canada in 1860.

It may be interesting to give a few particulars in regard to the steamers and engines referred to above. I am indebted to Captain R. Retallick of St. John, who has sent me, through Geo. H. Waring, grandson of John Waring, one of the pioneer engine builders referred to above, the following particulars:

The steamer "Reindeer," for service on the St. John River, was built in 1844. Her engines were compound, the high pressure cylinder being horizontal with Stephenson link motion and the low pressure cylinder oscillating. Captain Retallick states that this was the first compound engine that was run successfully (probably he means for marine service), but it must have been among the first compound engines built for any purpose. This engine was designed by Tippitts and Waring — built by John Smith at St. John, N.B., and must have been of good design and construction as it was transferred to the steamer "Antelope," also a river boat, in 1861 and later installed in the steamer "Admiral," which was broken up in the year 1915, so that this engine passed the scriptural "three score and ten."

The steamer "John Waring" was built in 1858 at Woodstock, N.B., by Mr. McConnel. The engines were built by John Waring, and had two high pressure cylinders. The boat was a side wheeler as the water is very shallow at Woodstock. The "John Waring" was launched under steam and came direct from Woodstock to Indiantown, just above the reversing falls at St. John, about 140 miles. She was considered very fast.

The next steamer, Captain Retallick states, was the "Anna Agusta," built at Fredericton. The engine was a horizontal low pressure, or single cylinder engine, placed on one side of the boat with the boiler on the opposite side and was built by Fleming and Humbert of St. John. She was a side wheeler also.

One of the earliest steamers was the "St. John," built at East St. John. She was a side wheeler. The engine was built by John Smith. Captain Retallick says it (the reciprocating part of the engine), looked like a saw mill gate or sash moving up and down. This boat was launched under steam and managed to paddle around into St. John Harbor under her own power, but the hull was so full aft that she would not steer. Later, after a new stern was added, making her about 24 feet longer, she worked satisfactorily.

George Fleming, of Dysart, Scotland, who served his apprenticeship at Dunfermline, grandfather of the present owners of the Phoenix Foundry and Locomotive Works, established at St. John in 1835, and built quite large marine engines for service on the St. John River, Bay of Fundy, and later for the Prince Edward Island service—two of these boats, the "Rothesay" and "David Weston" for river service, were famed all over Canada for their speed. The old records of the company show that Mr. Fleming supplied an engine to Brazilian Ansley in 1838, price 250 pounds, and in 1840 an engine and malt mill for 225 pounds, and an engine for George Younger, price 180 pounds. The Flemings are said to have built the first steam fog whistle used in any part of the world, which was designed by a St. John man, and was placed on Partridge Island, St. John Harbor.

In the early sixties and seventies, a number of well known engineering concerns in the Maritime Provinces built stationary steam engines for the many large saw mills in New Brunswick and Nova Scotia, as well as for factories, mines and various other purposes. Among the most prominent of these may be mentioned, Geo. Fleming & Sons, John Smith, Harris & Allen, and Allen Brothers, of St. John. The Pictou Foundry, established by Mr. Davies, Sr., in 1854, who came from the old country as master mechanic of the General Mining Association—I. Matheson, formerly located at Chatham, N.B., and later at New Glasgow, and his son W. G. Matheson. The Truro Foundry and Machine Company. The Burrell Johnson Iron Works of Yarmouth, N.S., which built tug boats and small steamers, marine engines of considerable size, waterworks engines, etc. The Montgomery Iron Works at Halifax and Moir Symonds. The Montgomery company built a few locomotives which were used on the Intercolonial Railway.

From 1885 to 1890 the use of electric power for lighting, tramways and other purposes began to develop extensively in the United States and to some extent in Canada. Among the first to foresee and take advantage of the increasing demand for improved high speed engines, suitable for driving electric dynamos direct from the engine shaft, was the Robb Engineering Company, of Amherst, N.S. This concern, working in collaboration with the General Electric Company, Westinghouse Company, and other manufacturers of electrical apparatus, succeeded in producing combined steam engines and electric machine in compact form, adapted to the various services for which electricity was required. The first of these engines was designed and built by the Robb Engineering Company at Amherst, N.S., in 1890-91 under the direction of E. J. Armstrong, who was a pupil of the late Professor John E. Sweet, of Syracuse, New York, one of the best known designers and builders of high speed engines and a great educationist in mechanical engineering.

Mr. Armstrong was able, during the few months he spent at Amherst, through his thorough knowledge of the interchangeable system used in building high speed engines and his natural ability as a draftsman and shop instructor, to organize a department of the Robb works so that they were able to build, with Maritime Province boys, engines for electric service which were equal to the best produced in the United States or elsewhere. He also enabled this Canadian shop to develop its own steam engineering and drafting departments in which engines were designed and supplied for electric work, not only throughout Canada, but, being among the first

in this field, was able to furnish engines of this type to Great Britain, Spain, Australia, India, South America, British Guiana and several of the West India islands. The exceptional compliment was paid to these works of receiving an order for a compound electric engine for use and educational purposes in the Manchester Technical School at Manchester, England.

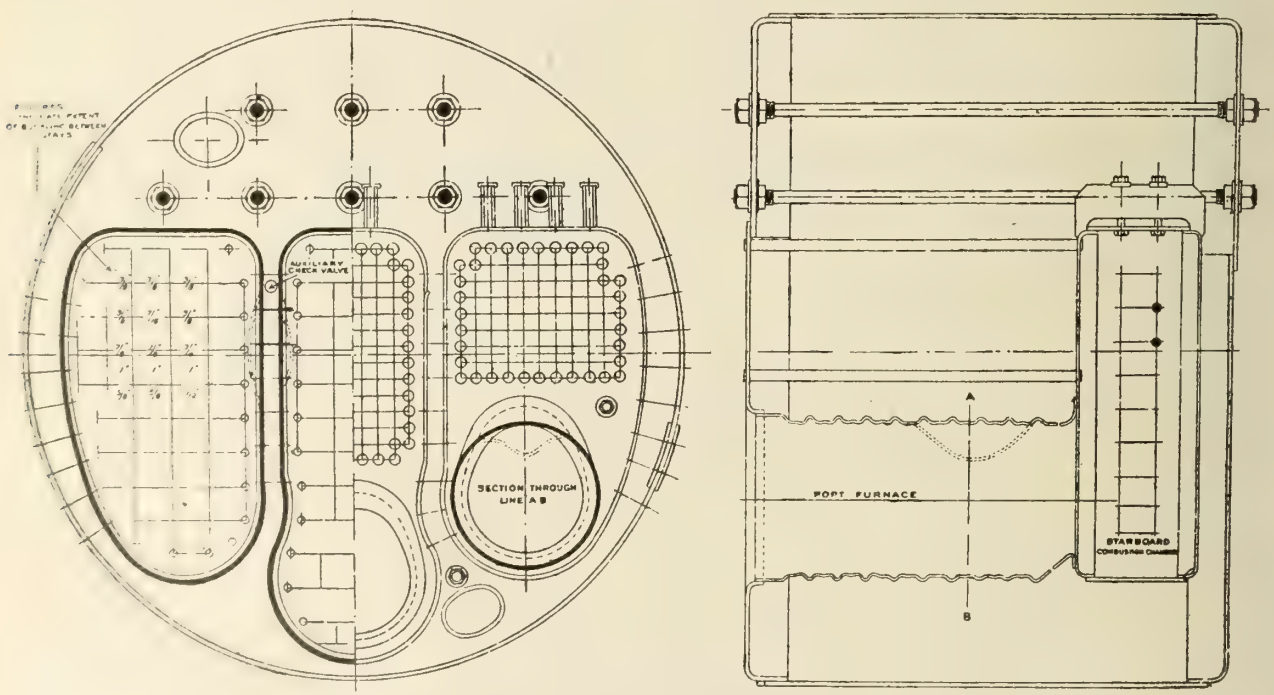
The steam turbine has to a considerable extent supplanted the reciprocating steam engine for large electric units where steam furnishes the motive power. Oil and gas engines are making considerable headway for the smaller units and to some extent for marine use.

The tremendous development of water powers in Canada has also restricted the use of steam engines for electric production, but as yet the marine field is to a very large extent held by the steam engine. In passing it will no doubt be of interest to mention that the triple expansion engines to be installed in Nova Scotia's two largest ships, 8,100 tons each, were built at Amherst. One of these ships the "Canadian Mariner" was launched from the Halifax Shipyards on the 4th of September, and the other is well advanced in construction.

There is no doubt that steam engines will continue to be built and used for ship propulsion for some time to come, or until the rapid changes constantly taking place in engineering construction bring forth something better or more efficient and economical.

Accidents to Scotch Marine Boilers

THIS report of enquiry under the Boiler Explosions Acts indicates the risk due to oil sediment deposit within the area of the heating surface and refers to an explosion from the port main boiler of the steamship "Willaston." The vessel was fitted with three single-ended boilers 15 ft. 6 in. diameter by 11 ft. 10 in. in length, each having three corrugated furnaces, 3 ft. 6 in. diameter, with separate combustion chambers, pressure 180 lbs. There was no donkey boiler. The port boiler, after being examined in April, 1919, was used during a voyage to Montreal and in port for auxiliary purposes till arrival in London on 5th July, 1919, when the fires were allowed to die out and the centre boiler was used in port. Ten days later the fires were again set away and when steam was ready this boiler was used as the auxiliary on the day before sailing from London on July 17th, when the steamer left at 3 a.m. with the gauge glasses showing nearly full up. At about 8 a.m. something went wrong with the port boiler, and the stokehold became filled with steam and dust. The chief and second engineers then tried to reach the boiler tops, but the steam drove them back at each attempt, the safety valves were eased and the engines opened out to full speed; when the steam was reduced the vessel was anchored. It was then found that the port furnace had collapsed near the tube plate end, and evidently the starboard chamber was leaking badly. It was resolved to return to London, where the boiler was carefully examined, when the wrapper plates of the centre and starboard chambers were found bulged, in addition to the port furnace damage. The demands on the steamer were such that time did not admit of the repairs being carried out then, and she sailed for Canada with the port boiler out of action. On her return a thorough investigation of the port boiler was made. The starboard and centre chamber wrapper plates were found to be bulged in from the top row of stays down a distance of about 2 ft. 4 in., the starboard chamber damage being the more severe. The flanges of the combustion chamber back plates were also set in. The starboard chamber plate had been forced over the stays, hence the serious leakage. The port furnace was pocketed about 9½ ins., starting from the back corrugation and embracing four corrugations. The heating surfaces generally were found comparatively free from scale, with no sign of corrosion on plates or stays. Careful examination of the damaged wrapper plates showed distinct signs of overheating, these being most pronounced on the starboard chamber, and there was on the right side a thin deposit of a black powdery substance. The auxiliary check valve is fitted 15½ ins. below the combustion chamber crown, on the back of the boiler between the centre and starboard chambers; no internal feed pipes are fitted, but the chest open-

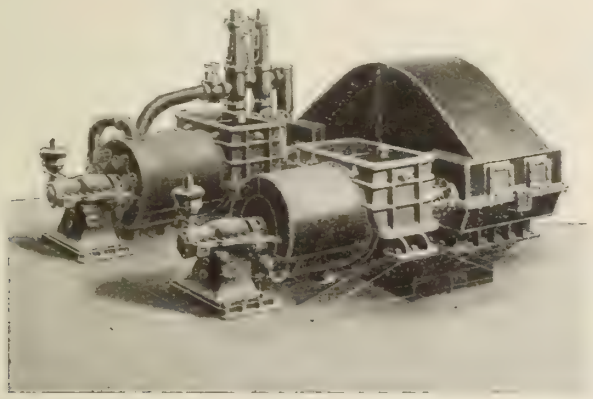


SHOWING LOCATION OF DEFECTS

ing projects about 7 ins. into the boiler with a closed end, and having four rectangular ports on the upper circumference through which the feed flows. An auxiliary condenser is fitted and the feed pump draws from it in port. It appeared from the position of the damaged plates relatively to the check valve that the feed water would be discharged so near that any greasy sediment would be deposited thereon, and the probability is that this is what happened and caused the damage. An analysis of the black deposit found on the plates confirmed this view. The deposit acting on the water side of the plates led to overheating and brought about the collapse. The damage to the furnace was due to the sudden outlet for the water at the combustion chamber plates fractured at the stays, leading to shortage of water on the furnace crown. The inquiry was conducted by Mr. A. H. Longstaffe, Board of Trade surveyor.

Geared Turbines for Swedish Battleships

EARLY in the coming fall, Sweden will try out its two new coast defense battleships, the Drottning Victoria and the Gustaf V. These vessels are 396 feet long, have beam of 64 feet, draught of 21 feet, displace 7,000 tons, and will have maximum speeds of 22½ knots. The main batteries consist of four 11-inch and eight 6-inch guns, and the main armor belt is eight inches thick.



GENERAL VIEW OF TURBINES

The propelling equipment of each of the ships consists of two Westinghouse turbines, which are rated at 22,000 s.h.p., and drive the two propellers through floating frame reduction gears. The turbines were built in accordance with Westinghouse designs by the Motala Verkstads Nya Aktisbolag, at Motala, Sweden, and the gears were designed and built by the machine works of the Westinghouse Electric & Mfg. Co., at East Pittsburgh, Pa.

Each turbine consists of two separate units, rated at 5,500 s.h.p. each, which drive a propeller through a common gear. Steam from the boiler enters the high pressure unit and passes through a set of impulse blades. It then divides into two parts, one of which continues through the high pressure unit, while the other goes into the low pressure unit. In both units the steam is fully expanded in reaction blading and passes into the condenser through a common discharge.

The chief advantage of this arrangement, which is known as the "divided-flow," is that all four units are available for propelling the ship at maximum speeds; but for ordinary cruising speeds, the low pressure units can be cut out, and the ship propelled by the high pressure units only. These, being of the complete expansion type, produce low speeds with good economy. Should an accident put a high pressure unit out of commission, the ship can be propelled by the low pressure units, which are designed to receive steam at boiler pressures. When any unit is out of use, it usually turns idly in a vacuum, but it can be mechanically disconnected.

The divided-flow turbine is not quite as efficient for full speed operation as the cross-compound turbine, in which part of the expansion of the steam is effected in the high pressure unit, and the rest in the low pressure unit. It is, however, more efficient at low speeds because one unit can be cut out, and this makes it especially applicable to naval service. In addition it can be operated at somewhat higher speeds, which tends to counterbalance its slightly poorer efficiency.

The performance of the Swedish turbines, with steam at 265 lbs., and a vacuum of 28.27 inches, is as follows:

Speed, knots ...	22½	20	12½
Propeller R.P.M.	200	177	115
Turbine R.P.M..	3,600	3,186	2,070
S.M.P.	22,000	15,000	3,150
Steam consumption—			
lbs. per S.H.P.	10.9	11.1	13.3

The water rate at 12½ knots is for operation with the high pressure units only. Were all four units, lightly loaded, used to obtain this speed the water rate would be about 17 lbs.

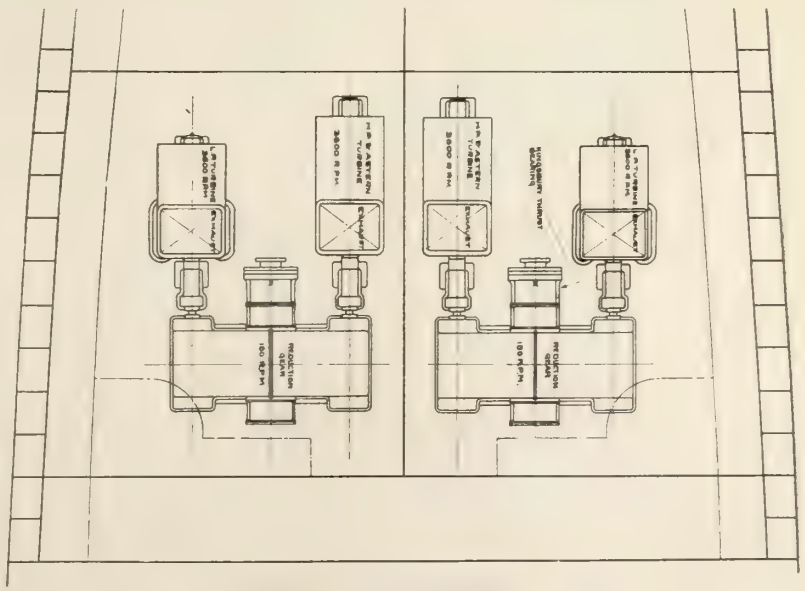


DIAGRAM OF ARRANGEMENT

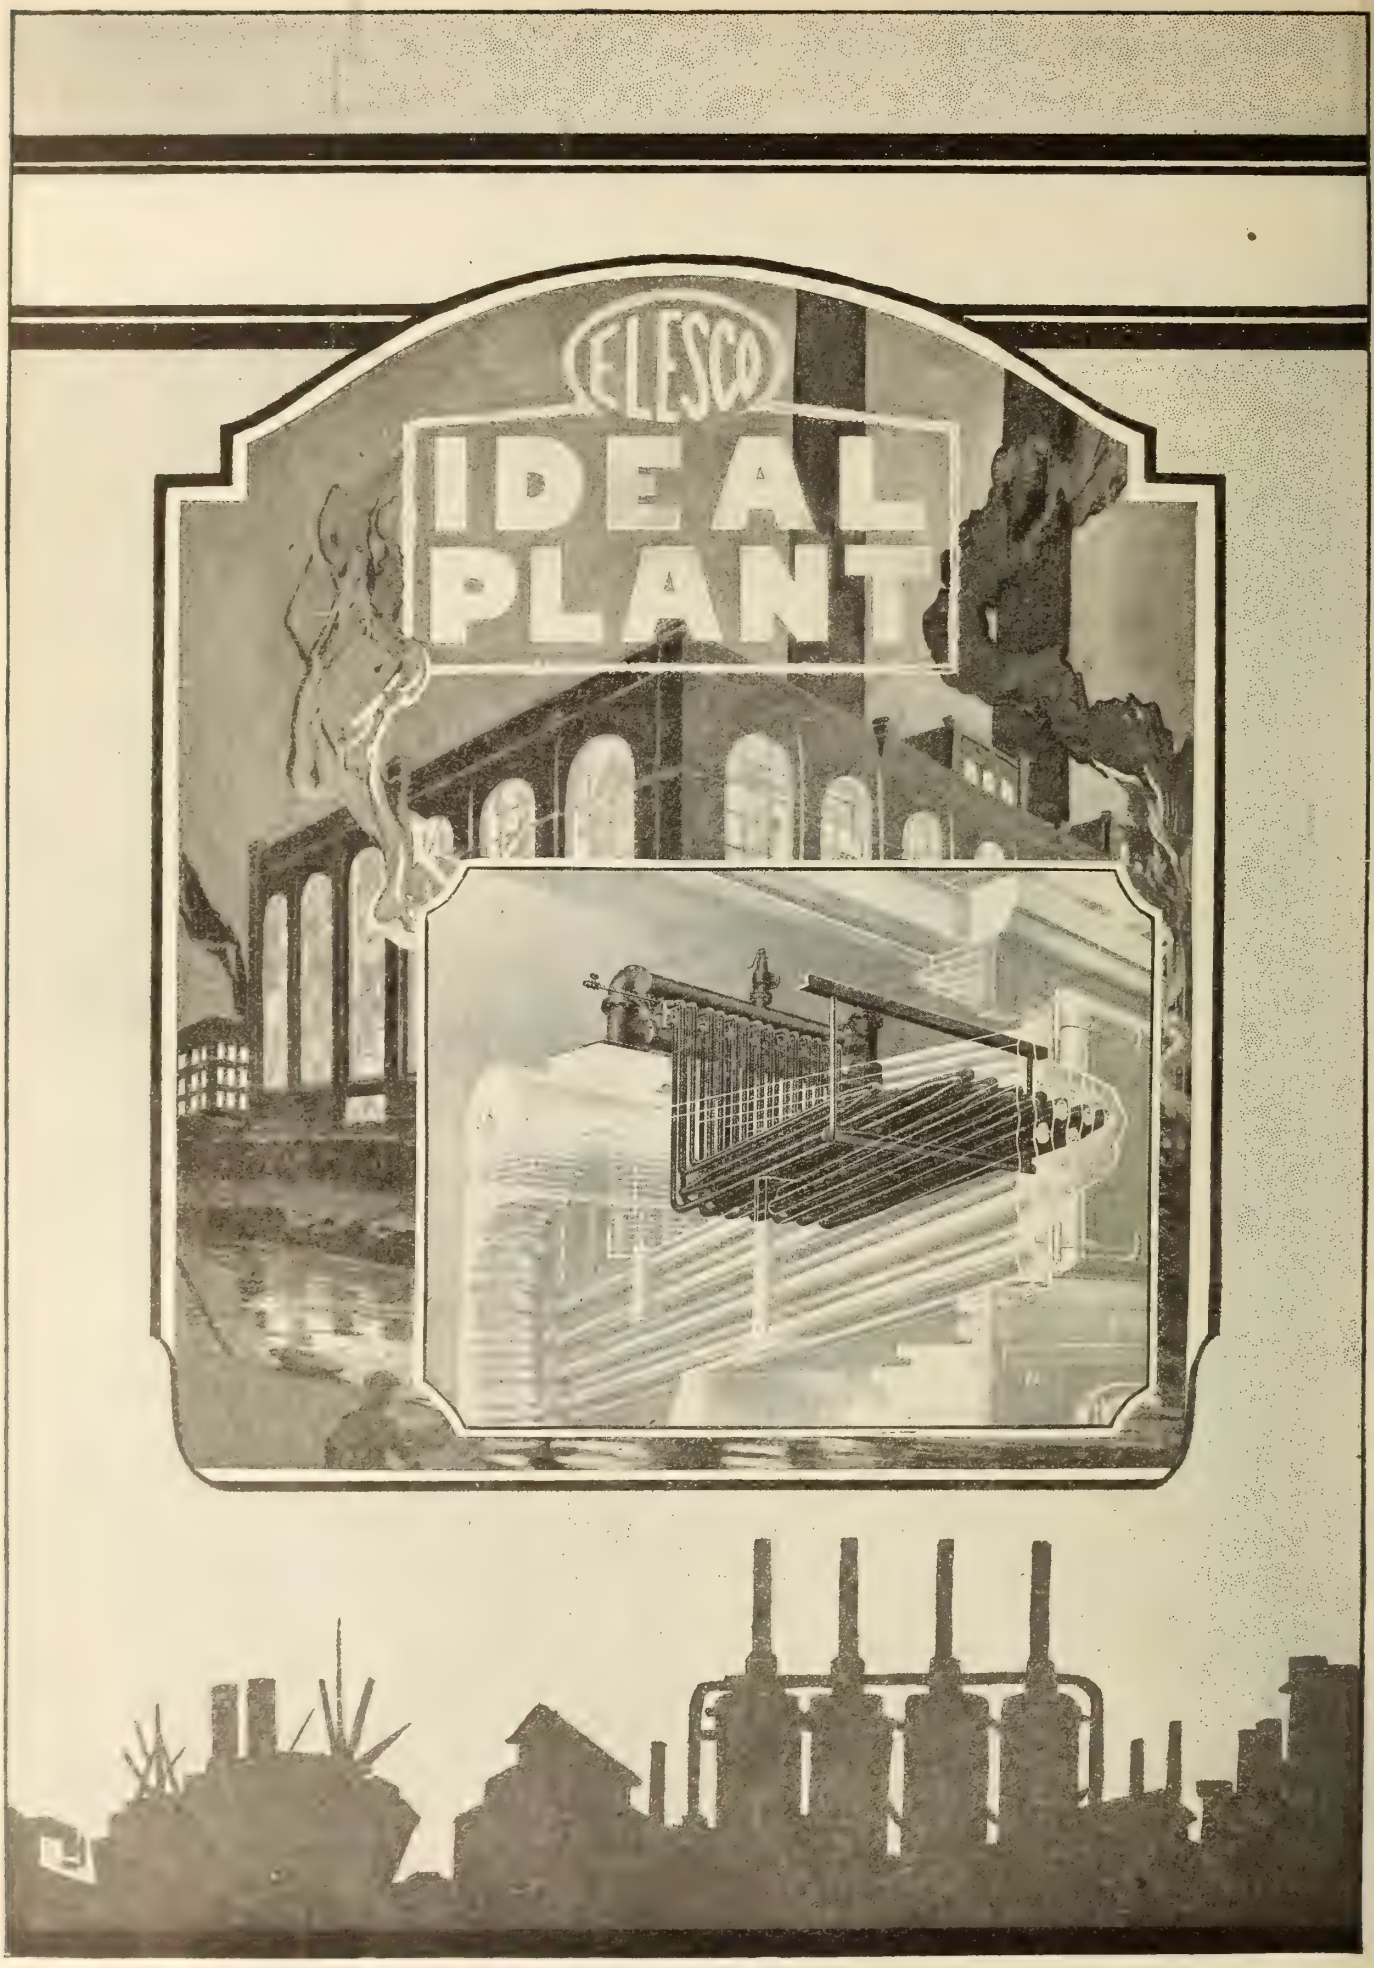
BRITISH AUTOMOBILE RESEARCH

Automobile engineers in all parts of the world will await with keen interest the receipt of a report recently completed by the research committee of the Institution of Automobile Engineers of Great Britain. The report deals with the physical properties of the ten automobile steels standardized according to the recommendations of the British Engineering Standards Association. Colored charts will be given showing the result of tests of tensile strength, hardness, and other qualities as affected by heat treatment. Automobile construction is becoming more and more scientific every day, and it is evident that British designers intend to keep in the forefront of the advance which depends upon a minute knowledge of the materials employed. Only a limited number of reports will be printed and early application is therefore advised.



ELESCO
IDEAL
PLANT

MADE IN CANADA

An Ideal Attained By
ELESCO SUPERHEATERS

The Correct Application and Use of Superheated Steam

Superheating is too vital a factor in power plant design to be treated in any other way than as an engineering problem.

In the design and installation of Elesco Superheaters 26 different factors are involved. The success of Elesco installations is the result of the correct interrelation of these factors.

Elesco engineers will study your conditions regardless of the size of your plant, and will co-operate with you in order that you may attain the one ideal toward which all discriminating power plant engineers are working—the economical, practical and reliable generation of power through the correct application and use of superheated steam.

An ideal is reached in plants equipped with Elesco Superheaters because guesswork has been avoided.

A Course of Instruction for the Graded Certificate

We Will in This Course Go Through the Mathematical and Theoretical Work to Cover Every Grade of Certificate Issued by the Ontario Board

By T. H. FENNER

WE have now got the shell of the boiler complete, except as regards the circumferential seams. In the earlier articles, it was shown that the stress on the circumferential seams was only half of that on the longitudinal seams. Therefore, we have to provide only for an efficiency of something less than 50 per cent. This means that we shall require only single riveted joints on the circumferential seams. Needless to say the circumferential joint is always a lap joint. The rivets should be spaced as closely as possible to maintain a steam tight joint, while still conforming to the requirements of strength. We must figure on having three diameters between centres of rivets, and with ⅞ rivets this would be 2⅝ inches, which would be the pitch. This would give a percentage of 66 per cent., which is ample, and the spacing would allow of a good steam-tight joint. It must be remembered that with a ⅞ rivet the diameter of the head will be about 1¼ inches. The space between rivet heads would then be 1⅜, which is not bad proportion. A larger pitch would increase the percentage of strength, but this is ample. It might be better to use a 15-16 rivet instead of ⅞, as this would allow more metal in the rivet head, which is subject to corrosion, especially on the two end seams. This would still leave ample strength in the seam, for with the same pitch, we would have 64 per cent., which is considerably more than half the strength of the longitudinal seam.

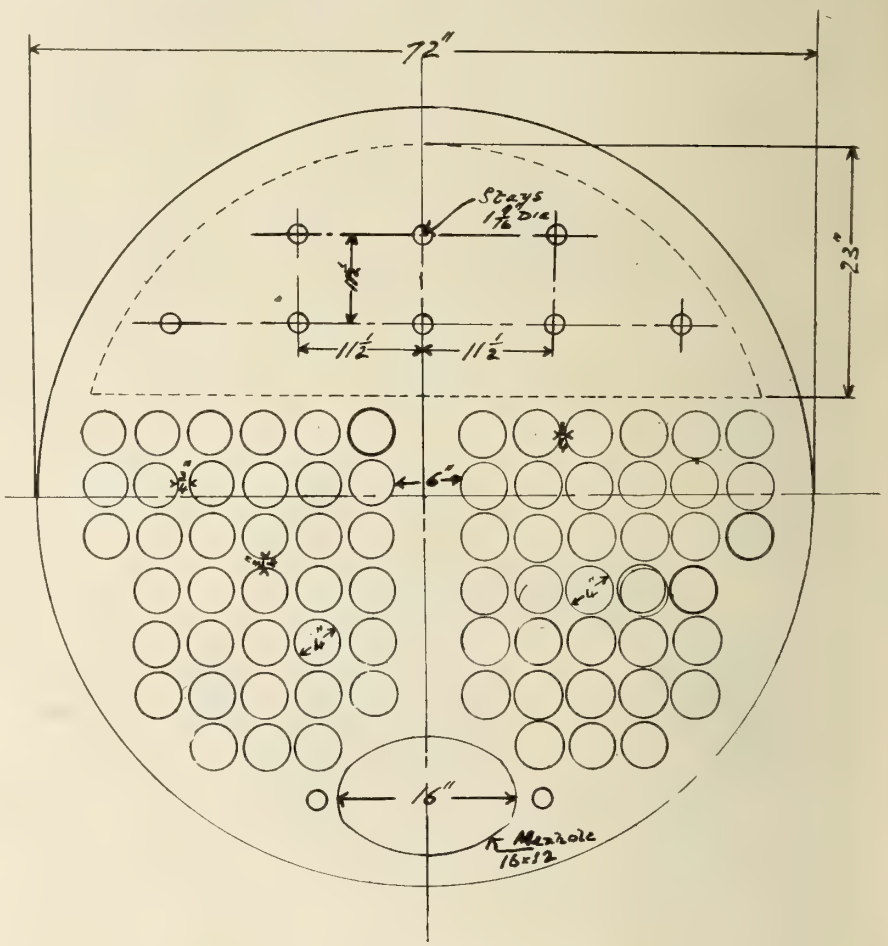
Laying Out Tube Sheet

We can now go about the laying out of the tube sheet; and the staying of the head above the tubes. Referring to our earlier articles, we arrived at 72 as the number of tubes required, and the diameter as 4-inch. As this size of boiler requires a manhole in the front, we have to allow room for this, and also for a man to enter the boiler and reach the back head. He should also have sufficient room to move with some degree of comfort.

The total area of the head or tube sheet of the boiler will be

72 x 72 x .7854 = 4071.5 sq. inches

while the area required by the tubes alone will be 4 x 4 x .7854 x 72 = 906.752 square inches. The minimum width of the ligament between tubes must be ¾ inch, or the sectional area of the ligament, which is width by thickness, must be at least 1-3 square inch, whichever is greatest. The manhole in the front head must be 12 x 16 inches, the long diameter, of course, being the horizontal one. The diameter of the boiler being 72 inches, we may consider the steam space as being 24 inches in height, or one-third the volume of the boiler. As the lowest point of water level must be always at least four inches above the top row of tubes, that will place the height of the top row of tubes at 28 inches below the top of boiler, approximately, or say eight inches above the centre line.



ARRANGEMENT OF FRONT HEAD.

In considering the area available for the tubes, it must be remembered that a certain amount of space is necessary between the tubes and shell, to allow for an ample circulation. This space should not be less than three inches. A certain amount of the head is supposed to be amply supported by the flange, and this amount, as found by the rules given, is also a fair guide for the space to be left between the outside tubes and the shell. This, of course, will reduce the area of head to be considered.

Area to be Stayed

The tubes are all that are necessary to hold the head where they are fitted, but the space above them must be supported by stays, and the area to be supported in this manner is also found by hard and fast rules laid down by the regulations.

Now the height of the unstayed portion of the head above the top row of tubes, we saw, was 28 inches, but this is not the height to be considered when finding the area to be stayed. The allowance made for the support of the flange, and a further allowance made for the support given by the top row of tubes must be deducted. The allowance for the flange is found by the following rule

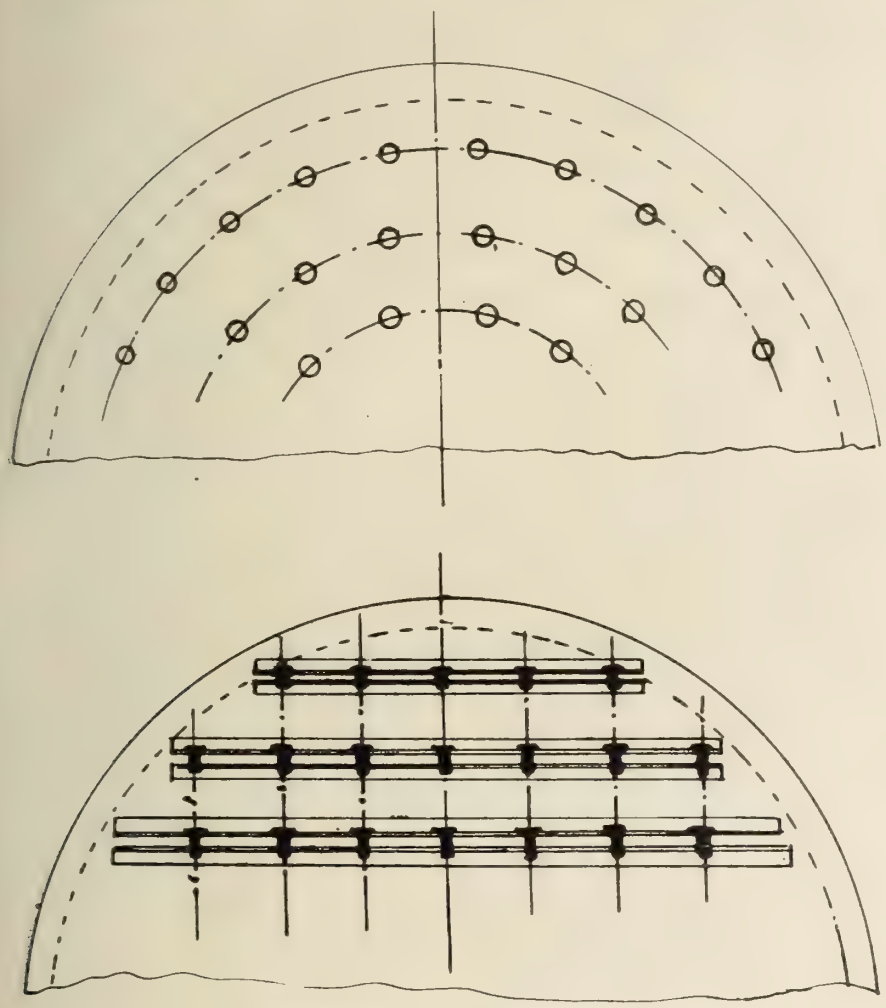
$$\frac{1}{2}\sqrt{\frac{112 \times t^2}{B}}$$

where t=thickness of head in sixteenths
B=working pressure.
If the value given by this formula is

less than the radius of the head flange, the latter value is to be used. We have so far not mentioned the thickness of the head. The thickness of the tube sheet or head is usually made 1-16 larger than the shell plate, so that we shall have a ½-inch head in this case. We then get

$$\tfrac{1}{2}\sqrt{\frac{112 \times t^2}{B}} = \tfrac{1}{2}\sqrt{\frac{112 \times 8 \times 8}{125}} = 3.78$$

or say 3¾ inches.



ALTERNATIVE STAYING METHODS.

The allowance for the support given by the top row of tubes is

$$\tfrac{1}{2}\sqrt{\left(\frac{112 \times t^2}{B}\right)} - \frac{d}{2}$$

where d=diameter of the tubes (outside).

This gives us 1¾ inches as the portion of the shell supported by the tubes. The area of a segment of a circle is obtained by the rule

$$\frac{4L^2}{3} \times \sqrt{\left(\frac{d}{L} - .608\right)}$$

where h=height of segment
d=diameter of circle.

Now our head is 72 inches diameter, but from this we must deduct 3¾ x 2 = 7½ inches, and from the height of 28 inches we must deduct 3¾ x 1¾ = 5½, which leaves us 22.5 inches as the height.

The area of the segment to be stayed will then be

$$\frac{4 \times 22.5 \times 22.5}{3} \times \sqrt{\left(\frac{64.5}{22.5} - .608\right)}$$

= 1012.5 square inches, say 1013.

The total pressure on the unstayed head will be 1013 x 125 = 126625 lbs. The stress allowed per square inch on steel stays is 9000 lbs., if above 1½-inch diameter, or 8000 lbs., if under 1½-inch diameter. Then the total area of stays required will be

$$\frac{126625}{9000} = 14.069$$

say 14.1 square inches.

If we are going to use direct stays we will be able to get in only about eight, and still leave room for a man to enter the boiler. Suppose we take a diameter of 1½, the area of which will be 1.7671 square inches. This, divided in 14.1 will be $\frac{14.1}{1.7671} = 7.9$, or a little under eight stays required.

We can also use the formula

$$\frac{A \times B}{N \times C} = \text{area of one stay}$$

where A = Area of segment;
B = Working pressure;
N = Number of stays;
C = 9000 for steel 1½ square inches net sectional area or over;
8000 for steel under 1½ square inches section;
7000 for iron unwelded;
5000 for iron welded.

$$\frac{1013 \times 125}{8 \times 9000} = 1.76 \text{ square inches.}$$

or 1.49 inches diameter, say 1½ inches. The area to be supported being 1013, and the number of stays eight, the area supported by one stay will be 1013 ÷ 8 = 126.625, and the pitch will be equal to the square root of that area. The square root is 11¼ inches, and in order to get a little more room we can make the pitch 11½ inches. In order to have a margin in the stays to allow for waste of material through wear and tear, the diameter may be increased to 1 9-16 instead of 1½.

Diagonal Stays

Instead of using direct stays we could use diagonal stays, of either round or rectangular section, and in some cases the gusset stay is used, although this is fast disappearing from use. When diagonal stays are used their area must be greater than that of the same number of direct stays. The reason is that the stress on the stay when diagonal is not a direct pull, but a combination of bending and tensile stress. The area of the diagonal stay will then be to that of the direct stay as the base of the triangle made by the diagonal stay is to its hypotenuse. In other words if the height from the stay on the head to top of head is say 20 inches, and the length from head to point of securing stay on shelf is 42 inches, then the length of the stay will be

$$\sqrt{(20 \times 20 + 42 \times 42)}$$

which is 46½ inches. Now if a direct stay would be good for 9000 lbs. per square inch stress, then the diagonal stay would be good for only $9000 \times \frac{42}{46.5}$ = 8130 lbs. per square inch. Taken another way, we might say that we have a direct stay of 1½ inches diameter, to be replaced by a diagonal stay. The diameter required for the diagonal stay will be greater. We may state it thus

1.5² x .7854 : area of diag. stay :: 42 : 46.5
= 1.959

and the diameter will be 1.579, or almost 19-32 inch.

Diagonal stays possess one advantage over direct stays, in that they leave the larger portion of the boiler over the tubes clear. This facilitates examination, which means very often

that the boiler receives better care than it would with direct staying, where moving around inside is difficult. When diagonal stays are used they are secured to the head and shell by riveting, double angle bars are riveted to the head, and the stay secured, by making an eye in its end, and passing a pin through angle irons and stay. These angle irons also serve to stiffen the head. Another method of staying is by gusset stays, where the angle irons are secured to both head and shell, and a triangular plate riveted to both angles. This method is but seldom used, and is mostly found in old boilers. A diagonal stay much used now is known as the Heuston stay, and is made of pressed steel of peculiar formation. It is of rectangular section, but a portion of the stay is doubled over on itself, longitudinally, as shown, which gives the stay a greater flexibility than a plain stay, while retaining its strength.

Stays that are secured by rivets to head or shell must have enough rivet area to be 20 per cent. greater than the stay section. When stays are secured by a pin passing through angle bars and stay the pin is in double shear, and can be reduced to 25 per cent. less area than the stay. This is not particularly good practice, as by leaving it the full size ample material is left to make up for wastage by corrosion.

When diagonal stays are used they are usually laid out on concentric circles round the head. As they are much smaller in diameter than the direct stay more of them must be used. In a boiler of the size we have been considering we would require about 15 or 16 stays.

Supposing we were to use diagonal stays of round section, with the feet welded to the stay. We could only allow 5000 lbs. per square inch on these stays, and we would therefore require 29.325 square inches. That would require about 20 stays 1⅜ diameter. As these stays would not be all at the same angle to the head, the relative value of

$$\frac{H}{L}$$

would be different at different rows and these would have to be reckoned on after their position was determined.

If gusset stays are used, they must have an area of 10 per cent. greater than that required for diagonal stays. The area of a gusset stay is the thickness of the plate, multiplied by it at the narrowest part. There must, of course, be sufficient rivet section securing the angles to head and shell to equal the stay.

The most satisfactory diagonal stay to use is the Heuston, on which the full value of 9000 lbs. per square inch may be allowed. By this method the least number of stays are required, and the requirements of ample strength combined with plenty room are fully met with.

It may be added here that when direct stays are used various allowances are given according to the method of securing them. If fitted with nuts inside and outside, and when washers are fitted, or doubling plates, the highest allowance is granted. The various allowances are stated in the Ontario boiler regulations, and will, of course, be available to candidates for examination when they are required for the problems.

POSSIBILITIES OF IMPROVED REFRACTORY MATERIAL

THE deterioration of refractory materials in boiler furnaces interests the operator primarily from a dollars and cents standpoint. The usual causes of failure whether they be physical or chemical seldom arouse a deep enough interest on the part of the engineer to determine the underlying reasons with a view to improvement of the product. If one material does not measure up to the standard of usual operation other brands are used, this cycle being repeated until something is obtained that suits. During this course of events if any real effort is made to solve the causes of deterioration, the effect on the industry is not particularly visible.

The reasons for this are probably many, but a few are ventured here. The development of more efficient furnaces in recent years has brought about higher maintained temperatures and other conditions of more or less increased severity. The refractory manufacturer on the other hand has apparently failed to parallel this development in the production of a material of a higher degree of refractoriness. Whether this is due to self-interest or because of the limitations of the fundamental principles of ceramics and chemistry involved, is hard to state, but the opinion of many engineers is that it is a little bit of both. Also it can be said that most engineers are more familiar with the physical performance of refractory material than with the chemistry involved, the latter being generally considered far-fetched. In consequence the co-operation between user and manufacturer toward improved material is limited in this respect, and it furthermore appears that the chemistry involved in the manufacture and use of refractory material is the province of the maker entirely. The ultimate service durability of the material is in the final analysis the gauge of its fitness.

The requirement of a high grade refractory material for boiler furnaces are probably quite familiar to most engineers and need no detailed explanation here. However, the chief requirements are physical and those dependent upon chemical phenomena appear secondary as far as actual practice indicates. The problem then is to obtain the limit of possibilities with the materials available and in this research chemistry is probably the best guide.

The refractoriness of a fire brick depends on its fusion point, in fact, the terms mean the same thing. The service of fire brick often depends on the percentage of silica and alumina in their composition and the conditions under which they are used. In some cases a high silica would be preferable and in others not, excess of silica in brick under conditions where there is excess heat with frequent coolings, failure is caused not due to refractoriness but to the destruction of the bond caused by the frequent expansion and contraction. The conclusions drawn from laboratory experiment tell us that the fusion point of a material is function primarily of the relative proportions of silica and alumina contained, and that the maximum possible is when certain definite percentage of these elements are combined. Also the amount of silica free or combined in the form of kaolin enters as a factor. The percentage of fluxing impurities if exceeding a certain degree affects the fusibility of a material adversely. Other compounds such as ferric and titanium oxides are supposed to exert certain specific influences depending on the amounts of each present. It is thus evident then that even with the highest grade of fire clay from a chemical standpoint there is an absolute limit to the possible refractoriness in fire brick due to the nature of things.

The experiments of Segar using pure mixtures of silica and alumina indicate that the maximum fusing point is about cone No. 32 (about 3,200 deg. F.), but this would be under circumstances that would not be likely with natural clays, due to impurities and the difficulty of obtaining uniform proportions. Actual practice in the later furnace development now has to deal with temperatures of 3000 deg. F., and over. The theoretical working margin of refractoriness is under these circumstances seen to be about 200 deg. and as a matter of fact, it is probably much less than this. All this would be the case where all requirements from a chemical or analytical standpoint were fulfilled to the highest degree possible.

These limitations do not take into account those that can be classed as physical, such as strength, texture, bond and uniformity of mixture, and of all the causes of deterioration and failure, more are traceable to these and other physical conditions than to chemical phenomena. A fire brick may fulfill all the requirements of laboratory and chemical tests and still be unfit for the service required of it. If, on the other hand, all physical requirements were fulfilled, the margin of refractoriness of a material is after all not necessarily increased.

Much has been said of the chemical deterioration of refractory material but the support of these contentions with coal burning stokers is rather vague. In the actual observation of performance, the general opinion seems to be that cause and effect from this source is minor and beside the real effects, the action of slag and spawling are perhaps the most objectionable conditions where

(Continued on page 475.)

The Operators' Point of View

RECHARGING DRY CELLS

While considering the making of things electrical, what about the dry cell? Numerous descriptions of how to recharge such cells with an electric current have been published. I have yet to see such a cell properly recharged by such means. The easy, best and cheapest way to recharge dry cells is as follows: Remove the filling, including the paper around the inside of the zinc shell. Save the carbon. Place three thicknesses of blotting paper around inside the zinc case. Dissolve some ground salammoniac in water and saturate the paper with the solution. Place the carbon in the centre and fill the space between the carbon and blotting paper with powdered coke, or even sawdust if coke is not to be had. Fill around at the top to a depth of 1-4 inch or so with wax, pitch or shellac. Solder any holes there may be in the zinc and the battery will be as good as ever.—J. N.

THE BELL RINGING TRANSFORMER

The article by Robert G. Flavius on page 448, Oct. 5th Power House, describing how to make a bell ringing transformer makes interesting and profitable reading for the man who has never studied such transformers. However, anyone who does not take a pleasure in building such articles will find that outside of the cost of material considerable work is necessary, and when work is not a pleasure it is simply labor. Such men can make a "spark coil" bell ringing transformer. An old spark coil can be secured from any auto repair shop for a small sum for much less than the material would cost to build one. By removing a few turns of the secondary winding, a perfectly satisfactory bell ringing transformer can be made about two layers of the outside winding removed would be about right. Although such a transformer will work all right in bell ringing it will not light a 10-volt lamp, but it will light a 2-volt lamp and will drive small electric toys. It is obvious that it will not be so powerful as the one described by Mr. Flavius.—J. E.

THREADED FITTINGS

Question:—Kindly let me know up to what size of steam pipe can threaded fittings be used, for a working pressure of 125 pounds per square inch.

Answer:—There is no limit as to size in using screwed fittings, provided they are of suitable material. The pressure you mention only calls for standard fittings. For convenience in erection, and in making repairs, connections between lengths of pipe are made with flanges instead of unions in all sizes above 2 1-2 inches, but the flanges themselves are of course screwed onto the pipe. Large fittings such as elbows and tees for pipe above 8 inches diameter should always be flanged instead of screwed. It is a matter of selecting the most convenient type of fitting for the job in hand.

HAMILTON NO. 2 LODGE MEETING

The last meeting of the Hamilton Lodge of the C. A. S. E. was favored by some distinguished visitors, in the persons of Grand Lodge President R. C. Leach, of Toronto, Past President A. M. Wickens and F. C. Harding, also of Toronto. During the evening two candidates were initiated and one new application was received. The educational side of the meeting was furnished by a paper on Combustion read by Grand Lodge Secretary L. J. Ellis, which will be taken up and discussed on the 1st November next after the regular meeting of the lodge. The visiting brothers addressed the lodge, and urged the Hamilton members to give Toronto a hustle. A committee was appointed to make arrangements for a return visit to Toronto.

SAYS COAL PRICES NOT JUSTIFIED

Values Should Come Down in a Short Time Is the Claim Now Made

Washington.—Reductions in coal prices may be expected soon, Charles L. Couch, president of the American Wholesale Coal Association, announced.

Mr. Couch, following a meeting of the executive committee of the organization at which the entire coal situation was canvassed, declared that it is the opinion of the committee that a great change in the whole coal market situation is imminent. He suggested to buyers of bituminous coal who have a month's supply in storage to confine their purchases to immediate needs.

MONEY FROM "WASTE" COAL

Close to the pit-head of many coal mines there lie huge "tips" of small coal. When coal of good quality was cheap, these tips were looked upon as waste because the heating value of the stuff was so small that no one would pay enough to cover the carriage. The huge increase in the cost of coal has, however, turned attention to the economic possibilities of these heaps of low-grade fuel. A large company has been formed to acquire the heaps and to transform the coal dust into briquettes of a form and composition suitable for domestic and industrial purposes.

May Buy Blower.—City Engineer Gray of Toronto urges that the city purchase a soot blower for the boilers at the beach pumping station. Mr. Gray contended that it would lessen the time needed to clean the boilers at the station. The recommendation was referred to the chairman and controller of the works committee and the city engineer.

POSSIBILITIES OF IMPROVED REFRACTORY MATERIAL

(Continued from page 474.)

the fusion point and all other properties of the material are satisfactory. It seems a rather imaginative deduction to connect these actions with chemical deterioration. Chemical analysis on material before and after failure is too inconsistent to allow of reliable conclusions. A favorite excuse of the manufacturer for premature failure of refractory material is that there is a chemical reaction between some element in the brick and some constituent of the flue gas. If this were true, no doubt some revision of the laws of chemistry would be in order.

The refractoriness of a fire brick cannot be entirely judged on chemical analysis of the material, although in a general way they should indicate whether the same is of a high or low degree. It is often the case that deductions from a chemical analysis are flatly contradictory to actual performance.

It would in general appear that the solution of the problem of making material of a higher degree of refractoriness is in some new compound having all the physical qualifications of natural clays with increasing fusion point. This means a manufactured substance. Some effort has been already made along this line, and many engineers look with increasing interest to the possibilities in the development of the new carborundum products.

100,000 Revolutions Per Minute

THE present-day tendency towards ever increasing speed has been often deplored by the more staid and conservative elements of the community. Where the endeavor to procure speed has only been actuated by a desire for new sensations, this disapproval is, perhaps, well merited. All speeding-up processes are not developed with such meretricious objects, and in the field of industry speed is a desirable thing, both in general production and in the details which make rapid production possible. From this necessity have arisen the various high speed machine tools, and high speed cutting steel, with which we have all become familiar in recent times.

To what extent this tendency has developed was forcibly brought home to us by an account of a high speed grinding spindle attachment recently exhibited by a well-known British firm of tool makers. Grinding is one of the operations in metal working where speed is of great value, and especially on small internal work, such as lapping gauges, internal tapers, bushings for precision tools, etc. The wheels employed are of necessity very small, and this permits of the attainment of high speeds. The higher the speed of the abrasive surface, the less tendency will there be for the surface of the metal being dragged, and thus roughened, a condition strictly to be guarded against.

Practice in grinding had reached a point where these wheels had been revolved at 75,000 revolutions per minute, which is a very respectable rate for any spindle to revolve. The spindle we are alluding to exceeds this speed by 33 1-3 per cent. That is, it is guaranteed to be capable of running safely at 100,000 revolutions, and has been run at a speed of 104,000 revolutions per minute.

This is getting to a point where the mind fails to grasp the significance of the figures involved at the first glance. Try to picture a small spindle and the wheel mounted on it which makes a complete revolution in just .0006 of a second. If the spindle on which the wheel is mounted is one-half inch in diameter, its circumference would cover a distance equal to 13,090 feet, or almost 2½ miles per minute. A locomotive with a 5 foot diameter driving wheel would have to turn that wheel 833 times a minute to attain the same distance in the same time. The spindle, of course, will, on the smaller sizes of wheels, be of less diameter than one-half inch, because it is very obvious that with a wheel of ½ inch or ⅝ inch diameter, one could not well have a ½ inch spindle.

The wheels for this speed must be of good construction, for they will have to resist the force tending to tear them apart, due to the speed. Of course, they will be of no great weight, probably averaging 2 to 4 ounces. Suppose the wheel weighs only 2 ounces, and is of one inch diameter, the force tending to make it fly off at a tangent, or the centrifugal force would be equal to about 18,000 lbs.

These figures seem hard to realize, and they serve to show what has been reached in engineering practice when such speeds can be employed with perfect safety. There can be no doubts as to the material employed, or the manufacturing methods used, when speeds of one hundred thousand revolutions per minute can be guaranteed.

Spontaneous Combustion in Coal Piles

EVERY year a considerable amount of heat units are lost by the heating and partial combustion of coal contained in storage piles. A large amount of this loss, like so many of the other wasteful losses, can be prevented if proper measures are taken in time. With the object of finding the proper preventive measures, the engineering experiment station of the University of Illinois has been conducting an investigation into the storage of bituminous coal, and has published a bulletin of the information thus obtained. The book is entitled "Bituminous Coal Storage Practice," and is Bulletin No. 116 of the Engineering Experiment Station. The authors are H. H. Stock, C. W. Hippard, and W. D. Langtry.

From a vast number of observations and answers to questionnaires from coal users all over the United States, a number of general conclusions have been drawn, and the suggestions contained in these conclusions will, if observed, tend to reduce the danger of spontaneous to a minimum. Those users of coal who store large amounts should procure this bulletin and read it carefully, but the general conclusions drawn should be of value to all coal consumers. The bulletin points out that storage is a good thing, in that it stabilizes the operation of coal mines, assists in equalizing freight traffic, and ensures the consumer a regular supply of coal. Attention is drawn to the necessity of preparing the ground for coal storage. This should be dry, with good drainage, although if it is necessary to instal artificial drains, these should be made around the pile and not through it, as putting a drain pipe through a coal pile is only a way of supplying air to support combustion, should it get a start. Furthermore, the ground should be well cleared, as this assists in reclaiming, and prevents the pucking up of a large amount of refuse when the bottom of the pile is reached. This is very wise advice. Space should be left, if possible, around the pile, so that the coal can be easily moved should it be necessary to uncover the seat of a fire. The summer months are

naturally the best time to store coal, but these are also the hottest months, and coal is likely to be at a high temperature when it is unloaded from the cars. Being a poor conductor of heat, the lower layers retain their high temperature, and are very liable to spontaneous combustion. Coal should, if possible, be piled in equal sizes, and sized coal should not be piled on top of slack or screenings, so that it is advisable to keep the piles as clear as possible of this class of coal. Of course, some piles are composed entirely of small sizes, and these require watching.

Coals high in sulphur are not desirable for storage, as sulphur, while not the chief cause of spontaneous combustion, as was previously thought, yet the oxidization of the sulphur not only produces heat, but also breaks the coal up into small pieces, thus indirectly assisting the heating by exposing more surface. There is no definite knowledge as to the effect of moisture in coal, the evidence being contradictory, but the repeated wetting and drying of coal increases its tendency to spontaneous combustion. It is suggested that it is not wise to put wet coal in a pile, or to store coal on a damp base, and, furthermore, a coal pile should be carefully watched after a snow or rain storm.

When fire is discovered the coal should be removed till the heated part is found, and this should be used at once if possible, or, if not, removed to another place. Only in case of actual necessity should water be used, although it is considered advisable to have hose laid handy in case of need. It is noted that according to American practice, ventilating the piles has not proved advantageous, but in Canadian practice it has. This is attributed to the fact that the Canadian system is more perfect. The advice regarding inspection is the most valuable part of these conclusions. The only real indicator of the condition of the pile is that of temperature, and when this approaches 140 degrees F. the pile should be carefully watched.

If the temperature continues to rise it should be moved when the thermometer shows 150 to 160 degrees, and the coal thoroughly cooled before being replaced in storage, or better still, be used right away. If the temperature rises very slowly, the pile must be watched carefully, but it need not be moved at as low a temperature as 150, as with a slow rise it may recede again. Coal is said to commence to smoke at 180 degrees, but it should be moved before smoking actually occurs, as when the coal is smoking combustion is pretty well advanced, as may well be imagined. Steaming is not to be confused with smoking. In fact, temperature tests should be carefully made at frequent intervals, and these alone used as a guide.

The bulletin not only contains much information on precautionary methods, but also on methods of unloading and reclaiming coal to and from the storage piles. The University of Illinois is conducting a very valuable work in the various engineering investigations they are conducting, and in making the results available to the whole engineering public.

An Unpleasant Experience

A RECENT news item contained an account of an action brought by the parent of a boy who had been inadvertently locked in one of the cold rooms of a packing plant for a period of twenty-four hours. The result of his imprisonment was to make him lose his reason, and substantial damages were sought by way of compensation. Of course, no monetary compensation could ever make up for the loss of reason, though it might, to some extent, for loss of earning power. The item recalled another incident of the same kind which did not end fatally, but gave the actors in it a very bad time for a few hours. The manager of a packing concern and his consulting engineer were making a tour of the cold rooms in the plant, and towards late afternoon entered a room the temperature of which was about 4 degrees above zero. The room was entered through an air lock, the doors being without handles on the inside, and as they did not intend to be more than a very few minutes inside, the doors were just pulled lightly to, without being fastened. Evidently no one saw them enter, but someone passing by noticed the doors were not tightly closed, and very carefully entered the air lock, and closed the inner door, and retired, closing the outer door after him. The two men inside having finished their inspection, arrived at the door on their way out and found to their horror that they were imprisoned. There was no means of communicating with the staff in the engine room, and no likelihood of anyone visiting the room for the next eighteen hours. There was, on the face of it, an excellent probability of their frozen carcases joining those put in there on purpose. The plant manager, unused to facing emergencies, promptly collapsed and became, for the moment, incapable of thought or action. The engineer, possessing a greater amount of self-reliance and initiative, promptly began to canvass means of escape. The doors were of one-inch wood, laid on studding, with an air space, making two thicknesses of one-inch flooring board, and the air space was tightly packed with insulation. Looking around the room, they were fortunate enough to find a piece of 4 by 4 lumber, which had been left inside by a providential piece of carelessness on someone's part. With this as a battering ram the inside door was attacked, and, after working in relays for about two and a half hours, an opening was made in the inner door large enough for them to reach through and knock the handle open. They were thus half-way out, and by this time fairly well exhausted. Their exertions with the battering ram had, of course, served to keep them from freezing, but in the intervals of working they cooled off rapidly, and while at work carried on with feverish energy. The same good luck which had attended their finding of the batten, again came to their aid, for the first thing the engineer saw when they got in the air lock was an expansion valve on the cooling coil for that room. Here he had an excellent means of calling somebody's attention to their plight, and he promptly availed himself of it. He opened the expansion valve wide, and the natural results in the engine room brought a puzzled engineer in quick time to look for the trouble. His surprise when, on opening the door, he was confronted with his bedraggled and very much frightened employer may well be imagined. That particular plant manager will not go into a cold room for any consideration that can be mentioned since that day, and he was many weeks before fully recovering from the experience.

Neither of these cases should have happened if ordinary precautions had been observed. It should be a fundamental principle among men whose vocation takes them into such positions to observe ordinary precautions. No man should enter a vault, cold room, steam boiler, gasoline tank, or any other place where he is liable to be inadvertently locked in, or become overcome with gas fumes, or scalded by the opening of a valve, without stationing a man at the entrance, with instructions to stay there till they come out. It is not always convenient to do this, but a bit of inconvenience is not to be balanced against danger to human life. Safety first is an excellent motto, even though, like many other good things, it is carried to ludicrous lengths by some enthusiasts. Presence of mind and resourcefulness are excellent qualities to get one out of a tight hole, but the same qualities exercised before getting into the hole obviate the necessity of getting out. Prevention is better than cure.

Cheapening Propulsion

THE progress that has been made in increasing the efficiency of ship propulsion, is well pointed out in connection with the launching of the Cunarder Scythia, at the yards of Messrs. Vickers, Ltd.

The old Scythia, which was in use in 1875, required 17 pounds of coal to move 100 tons of cargo one mile, whereas the new vessel burns only four pounds of coal or three pounds of oil while conveying the same weight at the same speed for the same distance.

Progress in New Equipment

FLUE CLEANING RATTLER

The Baird Pneumatic Tool Co., Kansas City, U.S.A., have placed on the market a flue cleaning rattler and unloader as shown in accompanying sketch. This machine is a friction and not a drop rattler. It cleans by friction, first removing the scale, then using this scale in powdered form as a scouring medium.

It is capable of handling, at one rattling, a full set of boiler tubes averaging 250 to 300 flues, cleaning them throughout their entire length inside and out, in from one to six hours, depending upon the hardness of the scale. Any length flues up to 24 feet can be cleaned, the adjustment for length being obtained by a moveable piston head in the drum. A six-inch play permits of a slight lateral motion, but not enough to allow the flues to become tangled and destroyed.

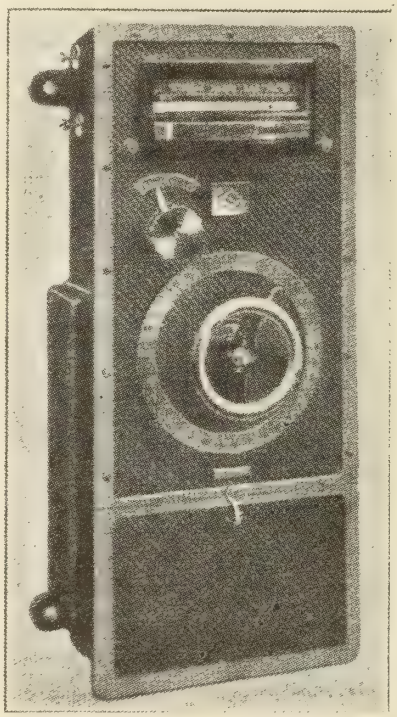
No dust is allowed to escape into the shop as the scale is gradually worked to either end of the rattler, and from there into the dust rooms provided for its accommodation.

The cleaned flues are unloaded by being pushed from the rattler by compressed air out through an end door into a push car, ready to be safe ended and installed.

Power is applied to rattler by either belt or chain, and in some cases by direct motor drive. The machine is adapted for all classes of fire tube boiler flues, handling large diameter super-heater flues as efficiently as the smaller sizes.

AN ELECTRICAL CO_2 RECORDER

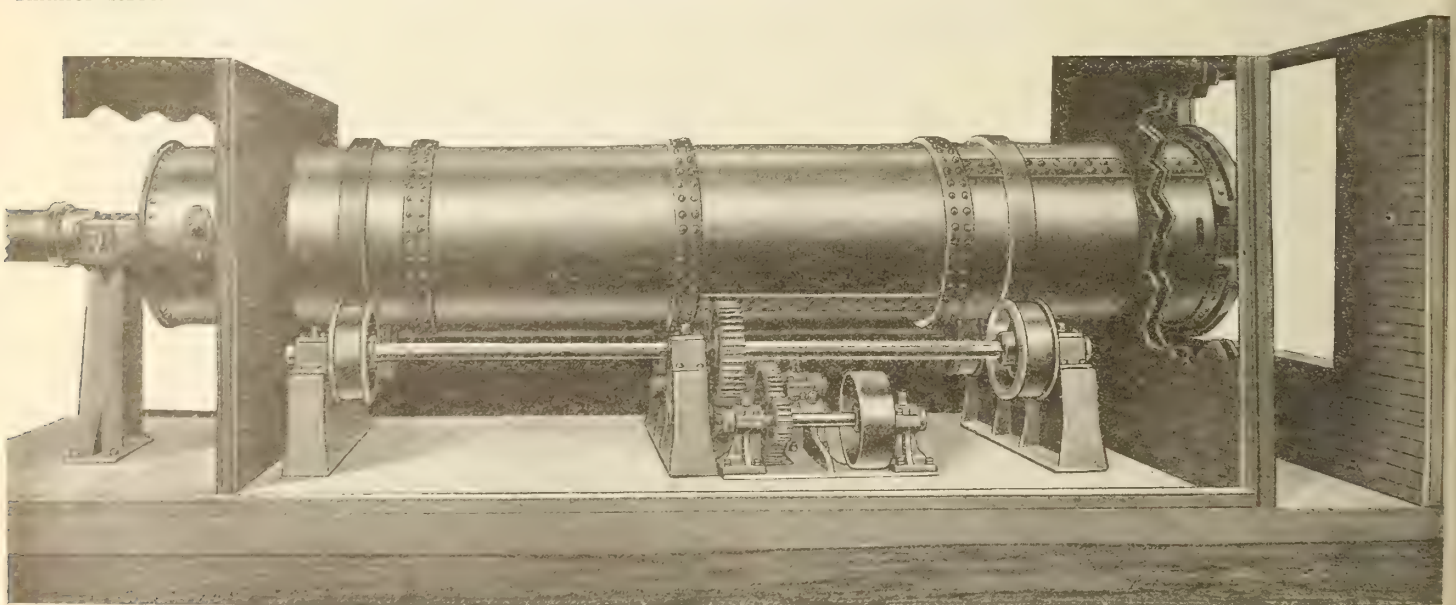
The Cambridge and Paul Instrument Co., of Cambridge and New Southgate, London, England, have been exhibiting



ELECTRICAL CO2 RECORDER

at the machinery exhibition at Olympia, London, a novel CO_2 recorder which uses no chemical absorbent. The method has been devised by Dr. Shakespear, of Bormingham University, and employs an instrument known as as a katharometer, which compares the composition of the flue gases to that of air. The instrument consists of two spirals of platinum placed in two cells formed in a copper block, and each spiral is connected in such a manner that it forms one of the arms of a Wheatstone bridge. If a current of sufficient magnitude is passed through this circuit the platinum spirals will be heated and impart heat to the cells, and if these cells contain gases of different thermal conductivities the spirals will give off their heat at different rates. The resistance of the spirals will vary with their temperature, and this property is taken advantage of by connecting a galvanometer across the circuit. This will give a deflection depending on the difference in the rate of coolint of the spirals, or in other words, the difference in conductivity of the gases in the two cells. If one cell contains a pure gas, and the other the same gas with a further additional constituent, the amount of the deflection of the galvanometer will be a measure of the additional gas. The difference in the thermal conductivity of air and CO_2 makes it possible to employ this method to determine the amount of CO_2 in the flue gases. The machine is described in detail in the "Engineer," as follows:

The katharometer and water aspirator are the two principal arrangements used. One of the cells of



FLUE CLEANING RATTLER AS INSTALLED INSIDE A PLANT WITH DUST ROOMS ON THE END.

the katharometer communicates with a chamber through which the flue gases are drawn by the water aspirator, whilst the other cell, which is filled with air, is connected to a tube which contains some water, so that the air in the katharometer is saturated. The method of applying the instrument to a boiler is clearly shown in the cut, from which it will be seen that a soot filter box containing glass wool is connected in circuit with the katharometer—for the purpose of cleaning the gas supplied to the instrument—by the vertical pipes projecting into the side flues. Details of the soot filter are also shown. A final filter is also fitted, as shown, next to the katharometer. The aspirator, it will be noted, is connected up to the water supply and works on the well-known principle. When a sufficient drop in pressure can be obtained behind the economiser a vertical pipe, shown dotted above the aspirating device can be carried directly to the chimney stack instead of using the aspirator for drawing the gas through the meter. Assuming the aspirator to be used, however, the flow of water is adjusted so that it runs freely out of the fine tube at the bottom. The function of the U tube shown on the front of the aspirator is to indicate the presence of any obstruction in the gas supply pipe, and when the aspirator is not working it indicates the chimney draft. The water consumption amounts to approximately five gallons per hour.

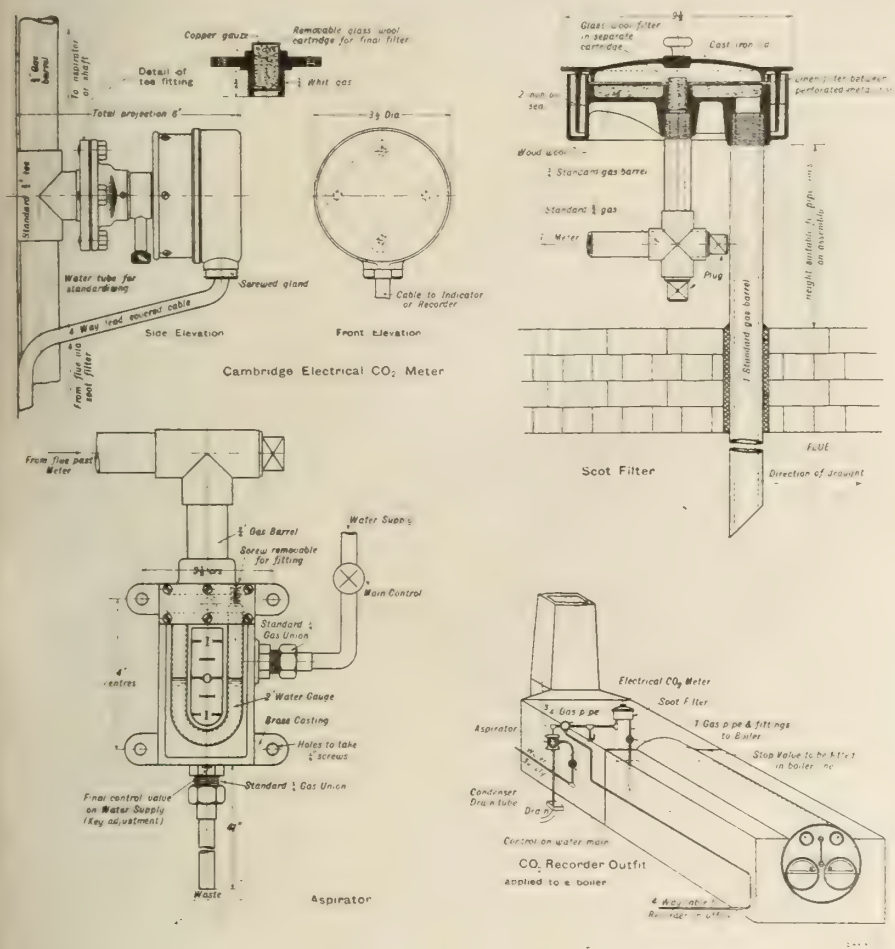


DIAGRAM OF METER CONNECTIONS.

The records are obtained by means of a recording thread galvanometer having a suspended coil and a pointer, which is depressed every minute and a-half on to a thread placed just above the revolving drum. This thread is impregnated with ink and every time it touches the chart it makes a mark which records the position of the pointer at the moment it touches the thread. Between the times of marking the pointer is allowed to swing freely to take up its new position. The series of dots obtained forms a record of the varying positions of the pointer, and because of the manner in which the charts are calibrated gives the percentage of CO_2 in the gas tested. The katharometer terminals are connected to the recorder by four-strand lead-covered leads, which may be of any desired length. Current for working the instrument is obtained from a 2-volt, 4-ampere-hour battery.

Electrical Distance Thermometer

Reference should also be made to the company's electrical distance thermometer, an example of which is shown. These thermometers may be used for measuring all kinds of temperatures, such as steam, oil, and air temperatures. Though the instruments were originally introduced for steamship use, they are equally applicable to ordinary power plants and, in fact, may be used in all places where temperatures have to be measured. The instrument from which the temperature is read can be fixed in any position, such as in an office, and by means of a plug switchboard or dial switch, as shown, a number of different circuits connected up to electrical thermometers can be joined to the instrument in succession, so that the switchboard operator can readily ascertain various temperatures without leaving the office or other place in which the indicating instrument is fixed. Other exhibits of the Cambridge and Paul Instrument Company included resistance pyrometers, thermo-electric pyrometers, an electrical pyrometer for locomotives, radiation and optical pyrometers, mercury-in-steel thermometers, dial thermometers of the vapour tension type, draught and pressure gauges, etc.

RISKED HIS LIFE TO SAVE WORKER

Construction Foreman on Steel Work Rescues Worker From Sure Death

It is understood that the name of Joseph Mouldey, 32 Carlton Street, Toronto, is to be submitted to the Royal Canadian Humane Society for an exceptionally brave act in saving the life of Frank Carvell, a fellow-employe of P H. Secord & Sons, where that firm is building the extension to the King Edward Hotel.

Carvell had ascended the 150-foot mast of the steel hoist to oil the mechanism at the top. While he had his hand in the machinery, the men below started the hoist going. Carvell's little finger and the ends of all the other fingers on his left hand were taken off.

Saved by His Glove

He shouted frantically, attracting the attention of the workers on the ground. Mouldey, who is foreman, immediately started up the mast, having only the cross iron work to climb on. Well before he reached the injured man the latter had fainted. His glove catching on a projecting piece of metal, he was hanging in the air.

Mouldey caught the senseless form, released the glove and started to carry Carvell down in his arms. Very slowly, Mouldey succeeded in getting down to within some thirty feet of the nearest platform, when other workers reached him to assist. He was so exhausted that he had to be practically carried down the rest of the way himself. When he reached the platform his face was bleached and he could not stand.

Men who saw it done did not believe that Mouldey could complete such a difficult journey with his heavy load, as the means of climbing were so awkward.

Cutting of Steel Plates, Castings and Billets

Rapid Cutting of Metals by Radiograph and Oxy-Acetylene Torch Are Described—This Matter Should Interest Steel Mills, Boiler Shops, Shipyards, Locomotive Shops, and Machine Plants.

By J. H. MOORE

TO the uninitiated, the accompanying illustrations will cause considerable surprise, and believing an article dealing with the details and uses of such a machine would interest our readers, we have prepared the following:

The machine to be discussed is known as a radiograph and is manufactured by the Davis-Bournonville Co., Jersey City, N. J. It is used for varied purposes as the photos will clearly show. To convey an adequate idea of the power adaptability of such a tool is impossible by illustrations alone. Seeing the machine in actual operation is a very different matter. Were one to go through some of the large shipbuilding plants and watch these machines cutting plates, angles, billets, heavy forgings, etc., etc., they could then realize its wonderful power.

Briefly the machine is of portable nature, weighing about 50 pounds and designed for cutting all thicknesses of steel from ¼ inch to 20 inches, or more. The speed of cutting varies with the thicknesses, but not directly. For instance, the cutting of billets 10 inches thick is accomplished at a rate of about five inches per minute and approximately the same rate is employed on thicker sections up to 12 or 15 inches. A billet 18 inches square was cut off at the League Island Navy Yard in 6½ minutes, and about the same rate would be used for cutting billets 20 inches thick. The reason for this is that higher oxygen pressures are employed and the combustion rate is maintained throughout the kerf of a heavy section at nearly, if not quite, the same rate for all thicknesses from 16 to 24 inches.

We do not know what the ultimate limit of thick cutting with this machine really is. It might be placed at 24 inches, but development now in progress will probably make it feasible to cut 30 inches, if not 36 inches. A reason for this indefinite limitation is an indefinite demand. The construction of large battleships and fast cruisers now in progress requires the use of forgings much heavier than ever used before, and this method of cutting is widely employed for such class of work.

The machine is used to cut either straight or curved lines, using a grooved track to guide for straight cutting, and a

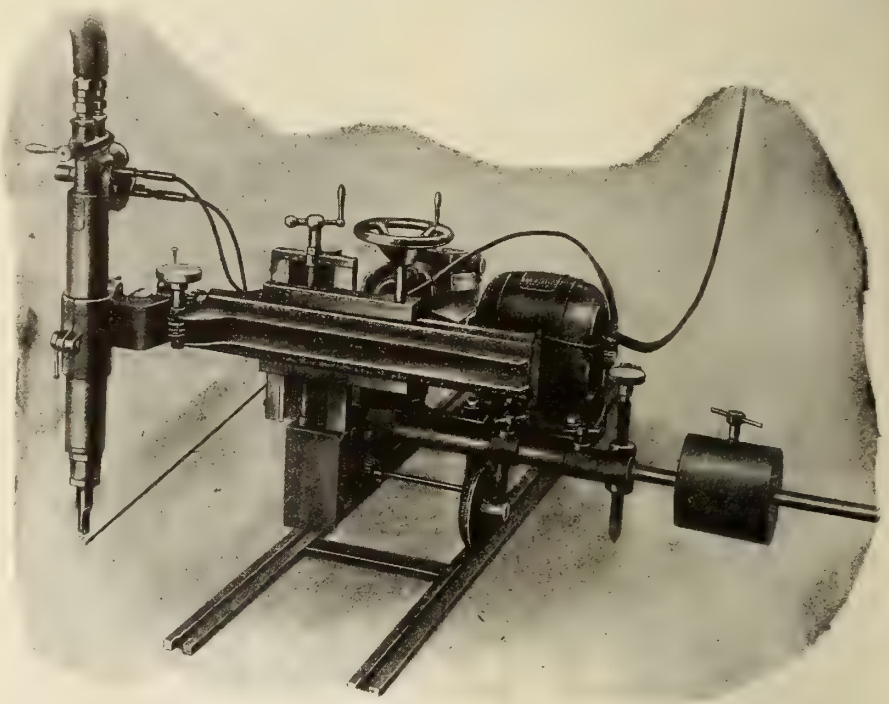

FIG. 1—FRONT VIEW OF MACHINE SET UP TO CUT TO STRAIGHT LINES.

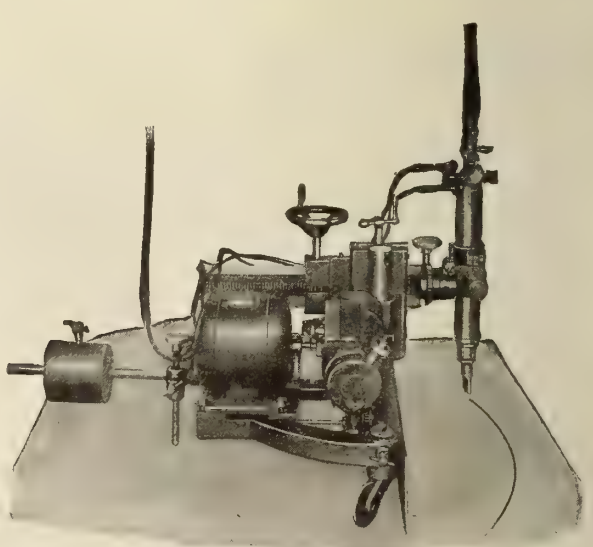

FIG. 3—THE MACHINE SET UP TO CUT CIRCULAR PATHS, USING SCREW POINT AS A POINT.

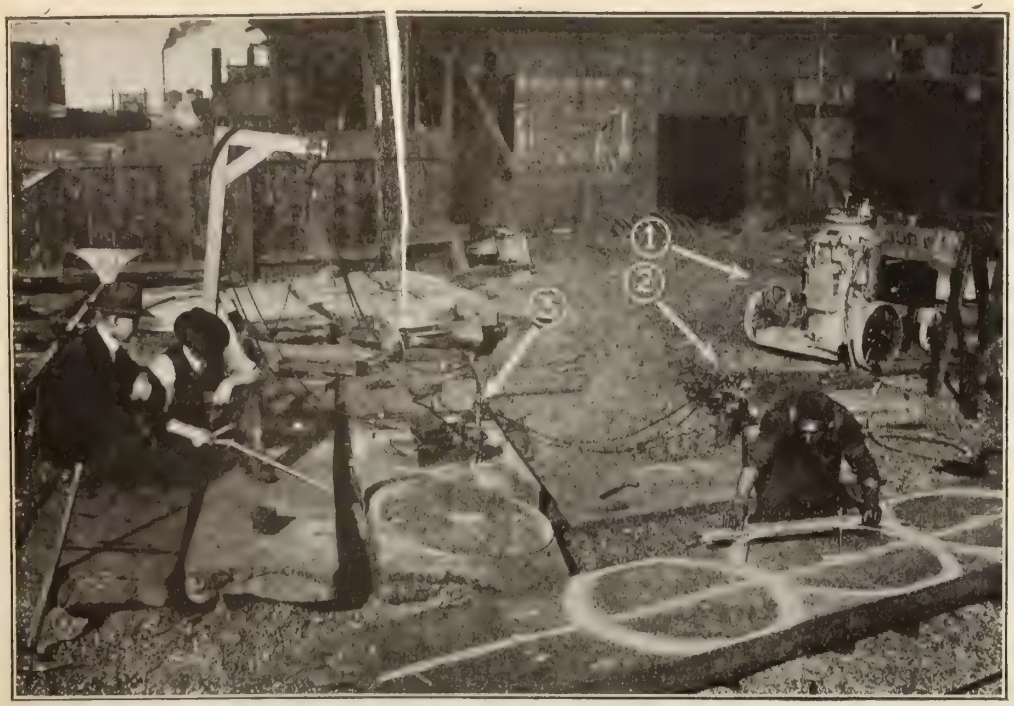

CUTTING DISCS 31 INCHES DIAMETER AND 9 INCHES THICK.

FIG. 5—A CLOSE UP VIEW OF DISCS SHOWN AT FIG. 4.

FIG. 6—CUTTING STEEL PLATE IN NEW YORK SHIPBUILDING YARD.

FIG. 8—TRIMMING HEAVY 24" "I" BEAMS. USING THE MACHINE FOR THIS PURPOSE HAS CUT THE FORMER COST IN SIX.

radius bar and center point for circular cutting. It is supported on three wheels, two of which are tractor wheels and the third a caster wheel. It carries a machine cutting torch and is fed along at a uniform rate by an electric motor working through a train of gears and driving the tractor wheels. A change gear feed box provides for various rates of speed suitable for cutting ¼-inch up to 20 inches thickness or more.

It might be well to add that the machine is fully covered by patents, both as to design and basic principle. Referring to Figs. 1, 2 and 3, we see the outfit set up for cutting to both straight and curved lines.

Cutting Straight Lines

Should readers ever use one of these machines, they should keep the following in mind. When a steel plate is to cut, it should be supported on blocks or horses a few inches from the floor. The supports should be so placed that the torch flame will not strike them in its path and the machine will not fall when the cut is finished. In some cases, it may be advisable to mark the the line to be cut with chalk, and prick punch it at intervals of a few inches, but generally this is unnecessary for straight cutting. The track supporting the machine should be laid on the plate parallel to the line to be cut and set six to eight inches away. When the position of the rack has been determined, a chalk line may be drawn along the side so that in case of being shifted accidentally it can be replaced to the original position.

The machine is now placed on the grooved track and connected to the motor with a flexible electric cord to the nearest lamp socket or source of 110 or 220-volt current, according to the winding of the motor.

The machine operates in either direction, depending on the setting of the reverse gear knob. The torch should be adjusted horizontally and vertically on the cross arm so that the tip is directly over the line to be cut and with the end about ¼ inch above the surface of the plate. The vertical adjustment depends on the style of tip and thickness of cutting. The acetylene and oxygen cylinders are placed alongside in convenient positions where the pressure gauges can be seen. The cylinder valves are next cracked and attached to the regulators. Connect the hose to the torch, red hose to acetylene and black hose to oxygen, taking care to blow out first to free the hose of dust.

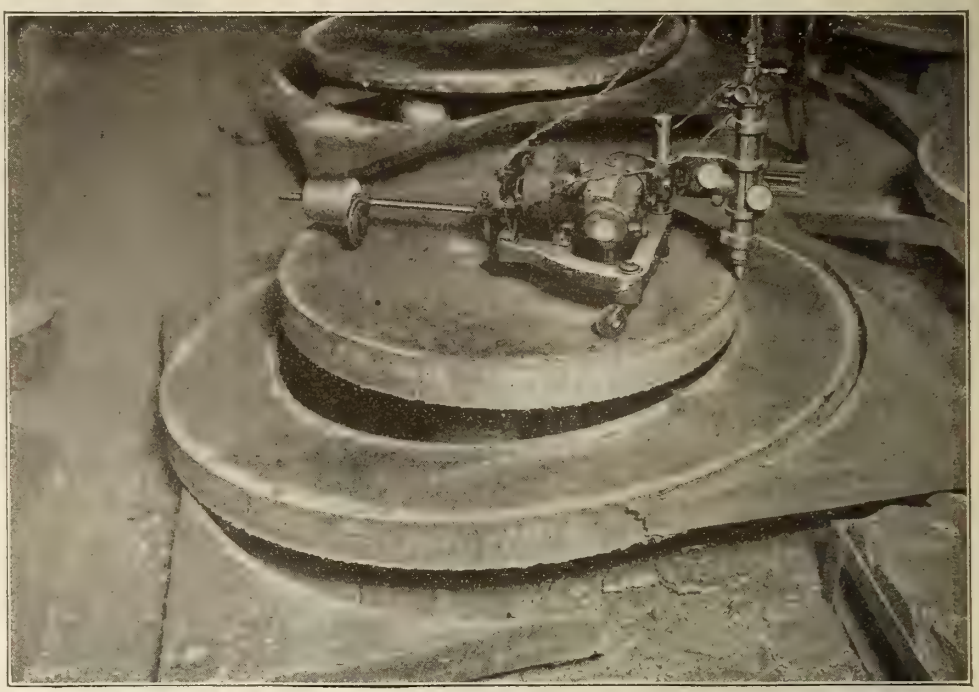

FIG. 9—AN EXAMPLE OF CIRCULAR CUTTING. THE PLATE IS 2½" THICK AND WAS CUT AT A SPEED OF 6" PER MINUTE.

Open the gas cylinder valves carefully, turning on the oxygen valve first. The regulator adjusting screw should be in the "off" position. Open the valve in the torch, adjust the acetylene working pressure with the regulator screw, and light the torch with the sparklighter. Then open the oxygen valve, and adjust the oxygen working pressure.

Next, adjust the preheating flame with the oxygen needle valve, making it neutral, or slightly oxidizing. Open the cutting oxygen valve when making this adjustment. Cutting should begin at the edge of the plate wherever feasible but if the pattern to be cut is some distance from the edge, the plate may be perforated with the flame. Preheat the plate to a high red or white hot temperature and then turn the cutting oxygen valve handle. Opening the cutting oxygen valve operates the switch turning the current on to the motor. The motor starts to feed the machine along at a rate that will depend on the setting of the gears in the feed box. The feed rate varies with the metal thickness, size and style of tip and oxygen pressure, and it should be determined before starting to cut the material.

Should the flame cease to cut, it may indicate that the travel rate

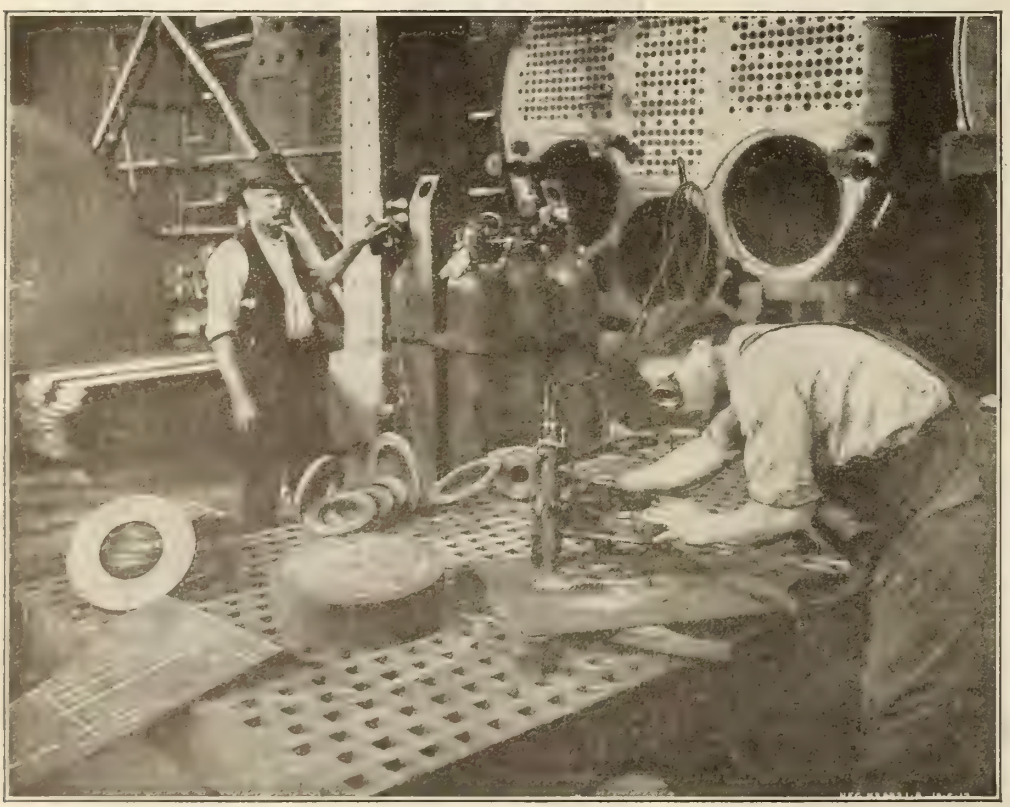

FIG. 7—CIRCULAR CUTTING. (Note the true shape and thickness of finished pieces.)

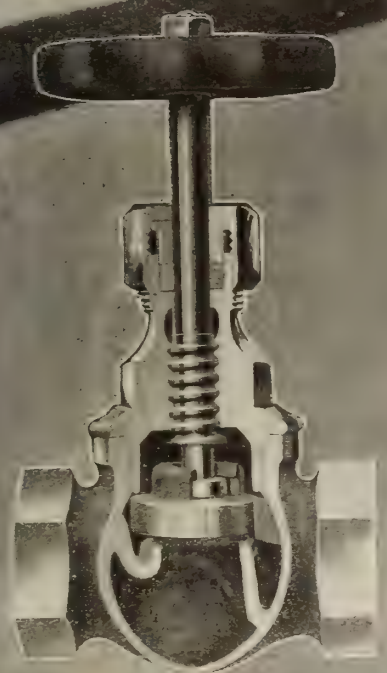
FAIRBANKS-MORSE



An Achievement in Mechanics

EACH individual department of The Canadian Fairbanks-Morse Company, Limited has given industrial Canada a new conception of achievement in mechanics. Each department has established a 100% quality and service standard. This is what enables Fairbanks valves to stand pre-eminent wherever valves are used.

When an engineer specifies Fairbanks valves, he knows that he has selected not only quality of material but workmanship that guarantees perfect operation.

He is satisfied with the reputation and service of the institution that stands behind them. He acknowledges an achievement in mechanics.

Wherever pipe lines are laid—in Canada's great industrial plants—in her immense water systems—in mines and mills—Fairbanks valves are giving a service that is marked by the 100% seal of quality, the standard of The Canadian Fairbanks-Morse Co. Limited.

Our nearest branch will give you the benefit of this service, Our experts will help you in selecting valves and everything mechanical that you require. Make our catalogue your buying guide.

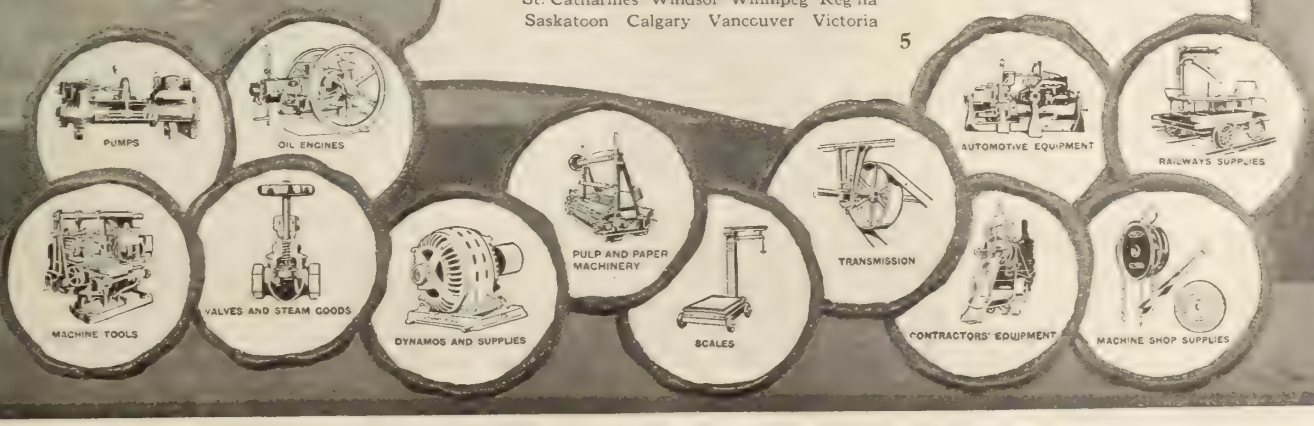

FIG. 10—AN 108,000-POUND STEEL CASTING. (Note the 36" main riser, also four smaller 8" ones.)

is too fast, in which case move the machine back to the termination of the cut, and start cutting again at a slower speed. On the other hand, too slow a speed may cause the cut to stop, and then the remedy is to increase the feed rate. The act of turning on the cutting oxygen starts the motor into operation, therefore do not turn on the cutting oxygen until the preheating flame has raised the metal to the burning temperature.

If the length of cut requires more than one section of grooved track, two may be used, which will serve for any length of cut, the first section being taken up when the machine has passed over it, and laid down in front of the one in use. In case of cutting that requires the machine to travel off the plate, it will be necessary to provide support for the track by laying another support alongside at the same level. To bevel a plate when cutting, adjust the torch sideways by loosening the swivel and clamping the torch at the desired angle. Notched, stepped or offset cuts can be made by stopping the feed motion by disconnecting one of the motor feed wires and feeding the torch sideways by hand the required distance, and then starting the feed again for straight-away cutting. Any combination of right-angle cuts can be made in this manner.

When starting a cut at the edge of a billet having a sloping side, the torch should be inclined parallel to the slope. When the cut has been started, the torch should be gradually brought to an upright position for straight-away cutting.

To Cut Curved Lines

Curved line cutting is done without using the grooved track, the machine being guided by a radius rod set in a punch mark at the center of the desired circle or arc. Lay off the required arc with dividers or a trammel bar, and prick punch the center of the arc to be cut. Set up the machine with the center point in the punch-marked centre, then adjust for the required radius.

The third wheel of the radiagraph (not shown in the illustration) is a caster that is locked with a set-screw for straight cutting. The set-screw should be loosened for circular cutting so that the caster will be free to swivel. Set the counterweight on the radius rod beyond the centre point and clamp it. The purpose of the counterweight is to hold the centre point down in the punched centre. If trouble is caused by the centre point slipping out of the centre, move the counterweight further out on the radius rod, and thus bring more pressure to bear.

Turn on the gases as directed for straight cutting and start the same as for straight lines. The radiagraph will automatically follow the curved line, swinging about the centre point. The machine is traversed by the outer tractor wheel. The rate of torch travel will vary with the setting of the cross arm and the position of the adjustable leg on the radius rod. It may be necessary to do some experimenting before the proper setting of the feed box gears can be determined. Remember that the torch, when outside of the tractor wheel, will move at a faster rate than on straight cutting, and it will generally be necessary to provide for slower feed rate, or to increase the oxygen pressure.

A circle having a radius greater than about 51 inches requires special radius rods made to order. Circles of very short radius are cut by setting the center point close to the frame and

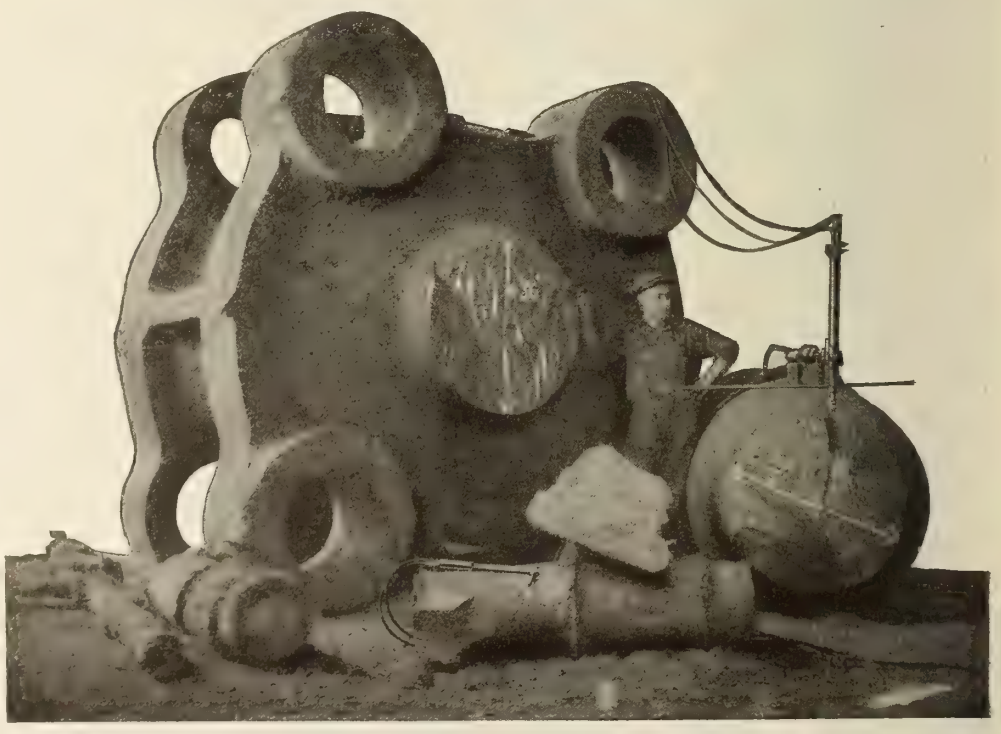

FIG. 11—THE RESULT OF A LITTLE OVER AN HOUR'S WORK. (Note the machine on top of larger riser to right.)

swinging the cross arm around the vertical post until the tip is on the inside of the radiagraph frame with the center point. This is done by unclamping the cross arm, litfing it up off the post, turning around over the frame and then slipping the socket down on the post and clamping. If the center point cannot be moved in to the desired position because of interference with the tractor wheel, remove it by loosening the clamp, holding it to the radius rod. The center point clamp can then be set close to the frame. This will usually give the short radius of action required.

It is possible to place the torch within about two inches of the center point but it is rarely feasible to cut circles of much less than six inches radius or twelve inches diameter. A faster feed rate must be set on the feed box than for straight cutting as the torch is traveling at a slower rate.

Cutting Combination Straight and Curved Lines

The path to be cut should be laid out and marked with the prick punch. The centers of the arcs should be punched and circled with chalk so that they can be readily located as the work proceeds. Lay out the work to make the straight cut first. Clamp the bracket on the radius bar at the correct position for cutting the arc of required radius, and screw the center point up so that it runs about 1-16 inch above the plate. The grooved track is not used when cutting to straight and curved lines on steel plate. The straight line cut is first made and as the center point reaches the punch mark it is quickly screwed down, catching the point in the plate. The machine then swings around the center, cutting to an arc without stopping and interrupting the cut. To cut to a straight line from the termination of an arc, unscrew the center point when the end of the arc is reached, which will permit the tractor wheel to rest on the plate, and then the machine will carry the torch forward in a straight line.

Having commented on the machine and how it should be used, let us discuss the illustrations shown. At Fig. 4, we see the machine cutting steel discs, 31 inches diameter, 9 inches thick, at the rate of five lineal inches per minute. This means that a cut is completed in 20 minutes. Some of the discs shown were 9 inches thick, others 5 inches, and from 25 to 36 inches diameter. At 1 is illustrated a D-B portable acetylene generator. At 2, some manifold oxygen tanks, and the radiagraph itself is shown at 3. A close-up of some of these discs is shown at Fig. 5.

Cutting steel plate with the oxy-acetylene flame in a New York shipbuilding yard is shown at Fig. 6. The machine can be clearly noted, and these plates were cut at speeds varying from 18 inches to 2 inches per minute on plate from ¼ inch to 20 inches thick.

Fig. 7 illustrates some circular cutting in the New York shipbuilding yards. The true and finished cut is self-apparent in this view, and the thickness is also considerable.

At Fig. 8 is illustrated the work of trimming heavy 24 inch. I beams, while Fig. 9 shows a good example of a circular cut in steel plate. Fig. 10 depicts a 108,000 pound steel casting with a riser 36 inches in diameter, weighing about 30,000 pounds. Two of the four smaller 8-inch risers can be noted clearly.

MALE HELP WANTED

MECHANICAL ENGINEER, PREFERABLY technical graduate, having steam-power-plant experience to assist in the preparation of technical-book manuscripts and in other steam engineering work largely of desk and detail character. Ability to write pure, simple, expressive English is essential. Teaching experience desirable. Must be accurate and thorough. We desire to locate a steady, well-balanced, painstaking engineer who does not ordinarily answer advertisements. To one who can satisfy our requirements we can offer a good future. Apply by letter only, in your own handwriting, giving age, education, experience (when and where you worked and what you did) and salary expected. Terrell Croft Engineering Company, 6600 Delmar Ave., University City, St. Louis, Mo. (p10h)

Don't Let *Old-Fogey* Ideas Rob You

Professor Langley, who invented the first heavier-than-air flying machine, used a propeller as the means of propulsion because, as he explained, there was no more sense in equipping an aeroplane with flopping wings, to imitate a flying bird, than there would be in using legs on a railroad train, to imitate a running animal.

He cut loose from a traditional fogey idea that a flying machine must flop, and his flying machine **flew.**

Our notions of steam trap construction were akin to Professor Langley's theory. We cast aside the old ball-float and other time-honored devices that often fail to operate—**and did some thinking for ourselves!** The result is the compact, dependable, highly efficient Steam Trap Sarco, designed on **logical lines.**

The Sarco is operated by expansion and contraction of a very sensitive liquid which opens the valve and drains condensate as rapidly as it collects, returning it to the hot well while hot. It closes immediately when condensate has drained, without loss of live steam.

Because it requires no storage space, for condensate, the Sarco needs no costly, complicated levers, gauges, packing or stuffing box. Simplicity of construction reduces its cost to about **one-third the price** of bucket or float traps.

You can install a Sarco anywhere on the line at any angle without change of piping. No supports, platform or floor space required. Sizes ⅜ in. to 3 in., for pressure up to 200 lbs.

Stop paying high prices for old-fashioned traps. Let us send you the Sarco on 30 days' free trial. Booklet J-12 on request.

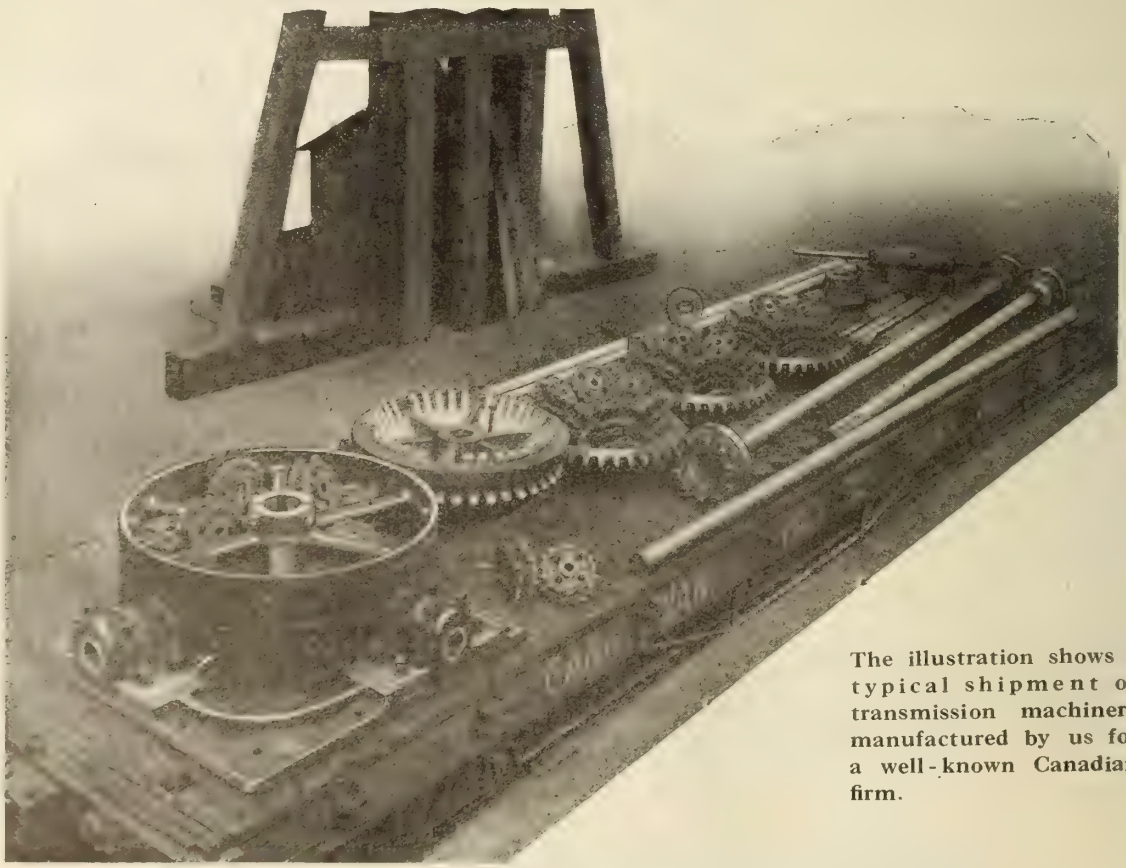
VICTORIA PRODUCTS

Victoria products cover requirements for pulp and paper mills, saw mills, stamp mills and mining machinery, special machinery, such as match, mica, paper box, etc.

The plant to-day consists of pattern shop, foundry machine shop, forge shop, heat treating and engineering department.

Speed on Rush Orders

The Victoria Foundry Company is famous for the care and speed which it bestows on all rush orders. This is one phase of Victoria service.



The illustration shows a typical shipment of transmission machinery manufactured by us for a well-known Canadian firm.

Victoria
Stop Log Winches

They are favorably known throughout the Dominion and may be seen doing satisfactory service at Magog, Buckingham, Temiskaming, High Falls, Latchford, Jonquières and Vancouver.

The Catalog of Victoria Foundry Products illustrates the Victoria Stop Log Winch and gives interesting information about its construction. Why not send for this catalog to-day?

Flutter Valves

We are prepared to supply these valves to suit almost any requirement. They are reasonably tight, positive in action, have a high safety factor and are easy to operate. See the Victoria Catalog for fuller details.

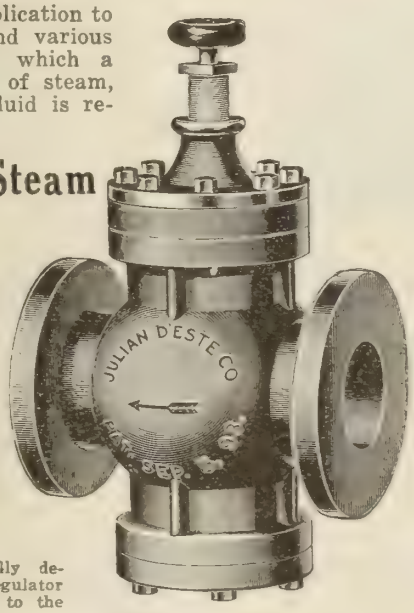
CURTIS Engineering Specialties

Universality!

For universal application to all the varied and various conditions under which a reduced pressure of steam, water or other fluid is required the

Improved Steam Pressure Regulator



has no equal.
It is compact and self-contained, without levers, weights or projections.
No glands or packing; no drip for leak of steam or water. Suitable for any boiler pressure; made entirely of metal: is a lock valve, very simple and sensitive.
Send for leaflet fully descriptive of this Regulator (contains price list) to the manufacturers.

Canadian funds are accepted at par at Montreal.

The Design of Moore Steam Turbines Prevents Steam Leaks

Ample surfaces at the joints have been provided to prevent leakage of steam—also the number of vertical joints have been reduced to a minimum. In a turbine having numerous vertical joints it is almost impossible to prevent leakage and consequent loss of efficiency in operation.

The careful designing to prevent all steam leakage is but one feature of Moore Steam Turbines. Send for our booklet. It explains fully the others.

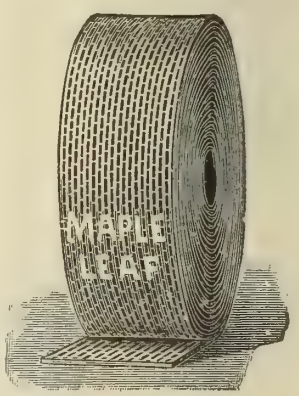
Dominion Belting Company, Limited
Hamilton, Canada

Sole Manufacturers of the celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing.

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.



"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber or Balata, as well as our own make.

Write us for prices, and if desired we will be pleased to furnish samples and further information.

A trial order will convince you of their utility.

QUALITY YORK SERVICE

York Uniflow Engines for Ice Making and Refrigerating Plants

One of the most important considerations in an Ice Making or Refrigerating Plant is the type of prime mover. An economical ice plant should have a dependable motive power, and one which will maintain a reasonable economy when called upon to operate over a range of from ¼ to 1¼ times the normal load.

It is well known among refrigerating engineers that the best compressor economy is obtained when evaporating pressures are carried as high, and condensing pressures as low, as possible. Even well balanced plants are forced to meet extreme seasonal conditions, with evaporating pressures varying from 20 to 30 pounds and condensing pressures from 85 to 225 pounds. These pressure variations and seasonal requirements of the Trade impose load factors of corresponding variation on the engine operating the compressor.

The Uniflow Steam Engine presents itself as the best solution of this difficulty

Board of Trade Building, Montreal

Assured

in driving generators, centrifugal pumps, fans, blowers and other auxiliaries goes hand in hand with

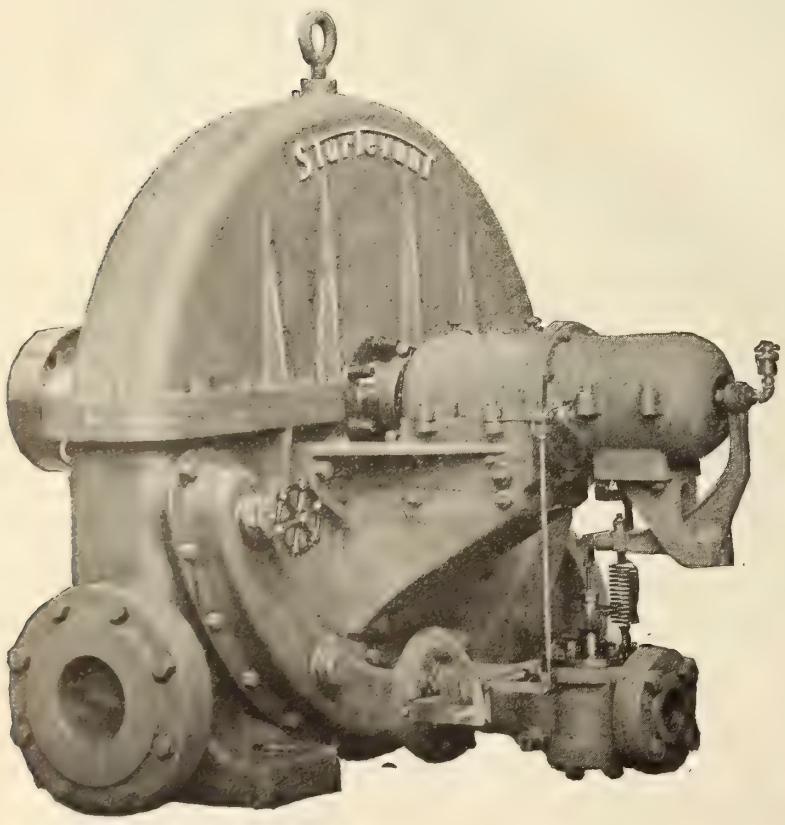
Sturtevant

(TRADE MARK)

Steam Turbines

They will operate continuously at a low steam consumption and very little wear.

The open hearth forged steel rotors are accurately balanced by scientific methods under skilled technical supervision. The buckets are carefully milled at an angle which has been determined by many years experience to be correct. They are smoothly finished to minimize steam friction.



The nozzles and reverse buckets are machined from tobin bronze and carefully fitted by ground joints. And one of these nozzles can be cut out of service by closing a hand valve in case less power is required, thus enabling the lighter loads to be carried without throttling the main steam supply. This insures good economy over a wide range in load.

Special attention has been given to the bearings which are self-aligning and provided with a liberal amount of oil storage to operate continuously over long periods without replenishing the oil.

The speed of the turbines is controlled by a centrifugal governor operating on knife edges which require no lubrication whatever.

B. F. STURTEVANT COMPANY

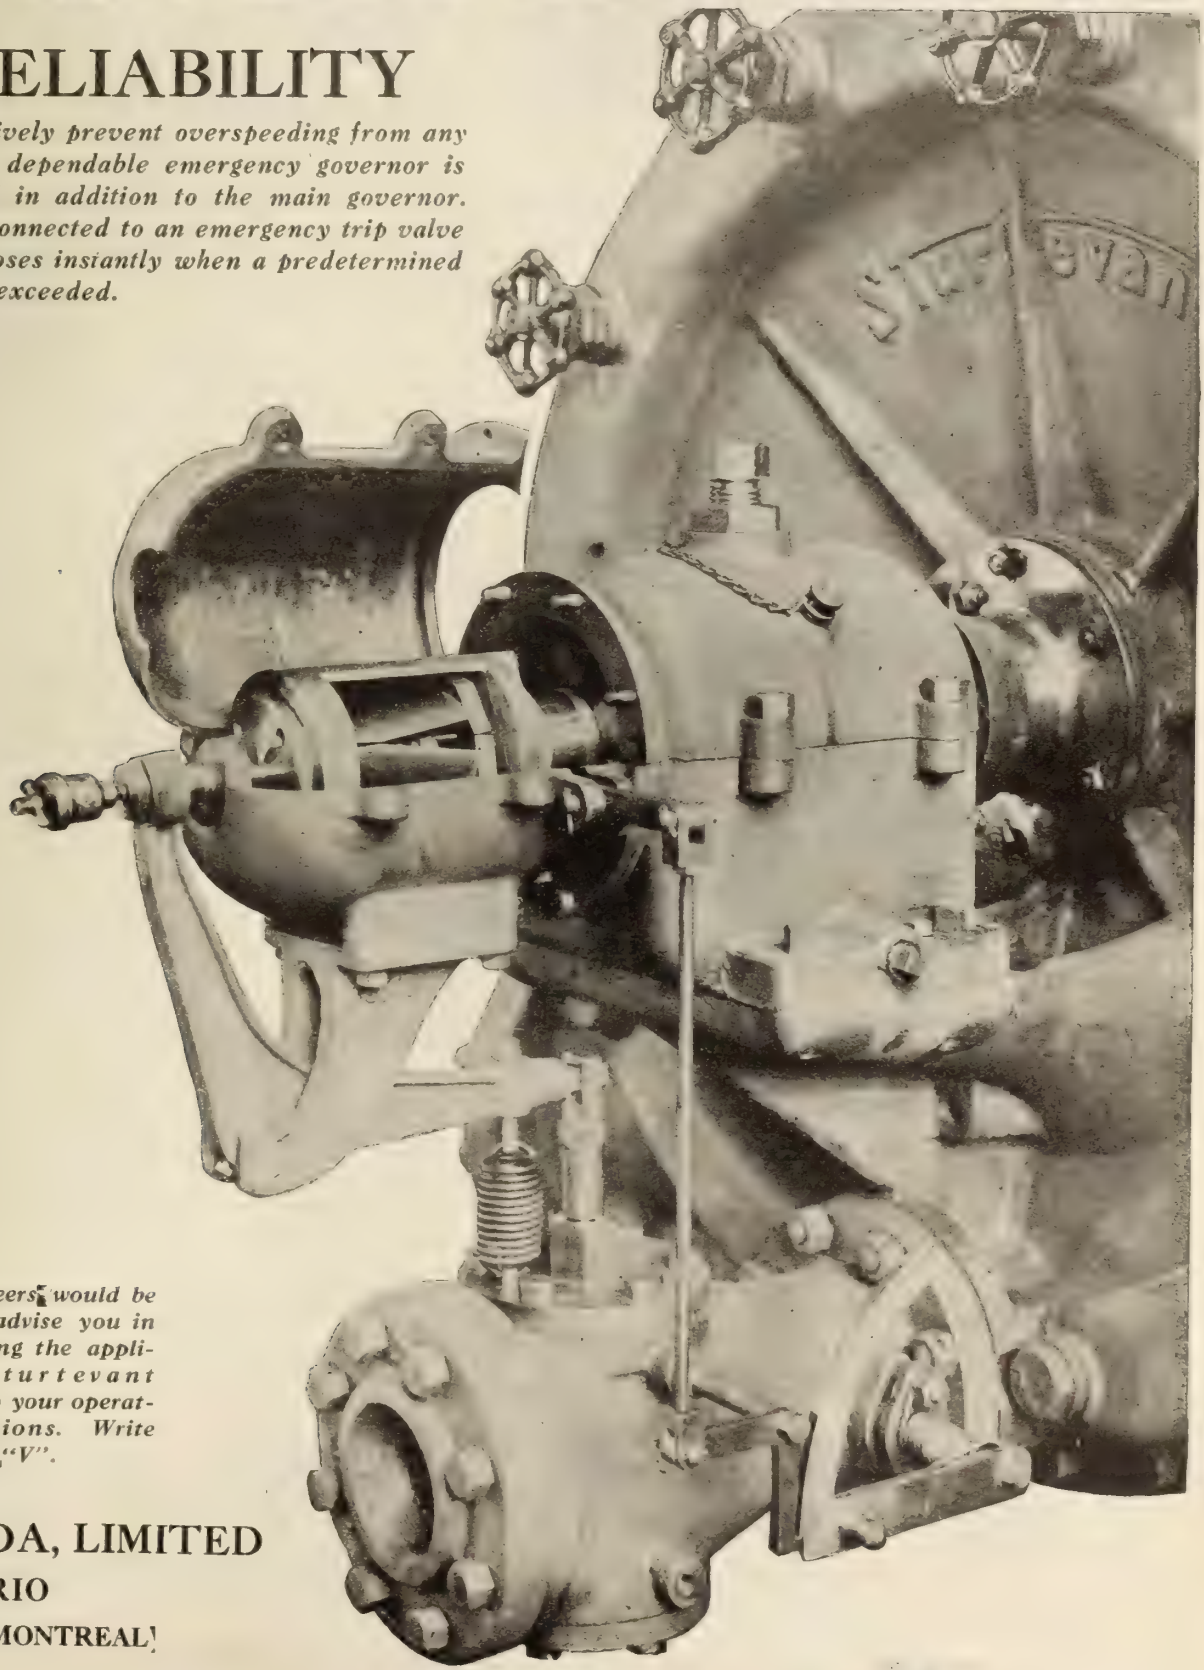
HEAD OFFICE AND WORKS,

SALES OFFICES:

Satisfaction

RELIABILITY

To positively prevent overspeeding from any cause, a dependable emergency governor is provided in addition to the main governor. This is connected to an emergency trip valve which closes instantly when a predetermined speed is exceeded.



Our engineers would be pleased to advise you in full regarding the application of Sturtevant Turbines to your operating conditions. Write for Catalog "V".

COPES BOILER FEED REGULATORS

Made in Canada
For Canadian Power Plants

The World's Largest Manufacturers of Feed Water Regulators Are Now Ready to Supply Canadian Power Plants with Regulators Made in Canada

The Canadian demand for efficient, up-to-date steam power plant equipment has grown steadily in the past four years. In the past year, the increase has outdistanced all others. At the present time more Copes Boiler Feed Regulators are sold per month in Canada than were ever sold in a year.

Hereafter the regulators used in Canada will be made in Hamilton, Ont. During the past few years the Canadian sales organization of the Northern Equipment Co., manufacturers of Copes Boiler Feed Regulators, has been materially strengthened. They are now

(Representatives in British Columbia)

The Copes Regulator Saves Both Fuel and Labor, and Increases the Peak Load Capacity of a Boiler Plant

It also reduces the wear and strain on boiler equipment and increases safety. The operation is entirely automatic. It is not affected by variations in the steam pressure, drafts or climatic changes. The rate of feed is varied to insure the highest economy in steam making where furnace conditions are bound to lag behind extremely irregular and unexpected fluctuations in boiler load, as is common in paper mills, steel mills and many other industries. No other regulator is so simple in construction and operation.

Ask for Bulletin D, giving full description, detailed information and technical data.

MONCRIEFF'S

"UNIFIC" GAUGE GLASSES

The British Navy uses "Moncrieff's" "Unific". It is the kind that lasts
It is a special feature of the "Unific" that it does not readily corrode; resists extreme changes of temperature and withstands the highest working steam pressure. In consequence it has a long life, justifies a higher price than the soda lime glasses, and is, indeed, the more economical purchase in the end.

Can YOU Afford It?

Soot and ash deposits on the fire surface of boilers cause a loss of millions of dollars annually.

Your proportionate share in this loss depends upon the number of boilers you operate, the cost of coal, and the degree of cleanliness obtaining.

Suppose you have four 500 H.P. boilers. Normally these will require 4 tons of coal per hour, or 20,000 tons of coal per year on a 5,000 hr. basis. At present prices, this coal probably will cost you $100,000 per year.

If you customarily allow your boilers to get in the condition shown in the picture before cleaning them, your loss is anywhere from $10,000 to $20,000 or more per year.

If you clean your boilers regularly and conscientiously with the hand lance, your loss is from $4,000 to $8,000 per year, depending upon the skill of the fireman.

If you clean your boilers with Diamond Soot Blowers you incur no loss, but get value received in steam (within the limitations of your furnaces and boilers) for every dollar spent for coal.

Best of all, Diamond Soot Blowers cost but a fraction of the annual saving.

Ask for Bulletin 280.

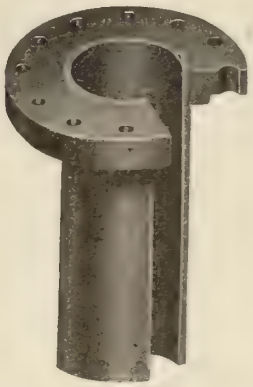
P&H FLANGED PIPE JOINTS



SCREWED

P-H LAP

P-H LAP FLANGES, for any service, have proven to be the best yet designed, and they have many advantages over other styles. The pipe is not weakened by cutting into the wall as when using screwed flanges. The gasket bears on the face of the lap and absolutely prevents leakage through the bore of the flange. The hub of the flange is bored slightly larger than the outside diameter of the pipe so that the flange will swivel readily and accommodate itself to any slight variation in the position of the bolt holes, an advantage which is obvious to the fitter and eliminates torsional strains in attaching.

Mueller Tapping Machine No. L.

Makes taps from ⅜ to 2 inches in all sizes of pipes under pressure. The Goose Neck is swiveled, turning to any position to allow ease in operating the Ratchet Handle. The special Mueller Oiling Device supplies oil to the tool through the Gas Cylinder.

Mueller Gas Tapping Machines are made in eight different patterns for tapping open gas mains, or mains under pressure. Over 90% of Tapping Machines in use are Mueller built—proof of their efficiency and superiority.

Write today for detailed descriptions and prices.

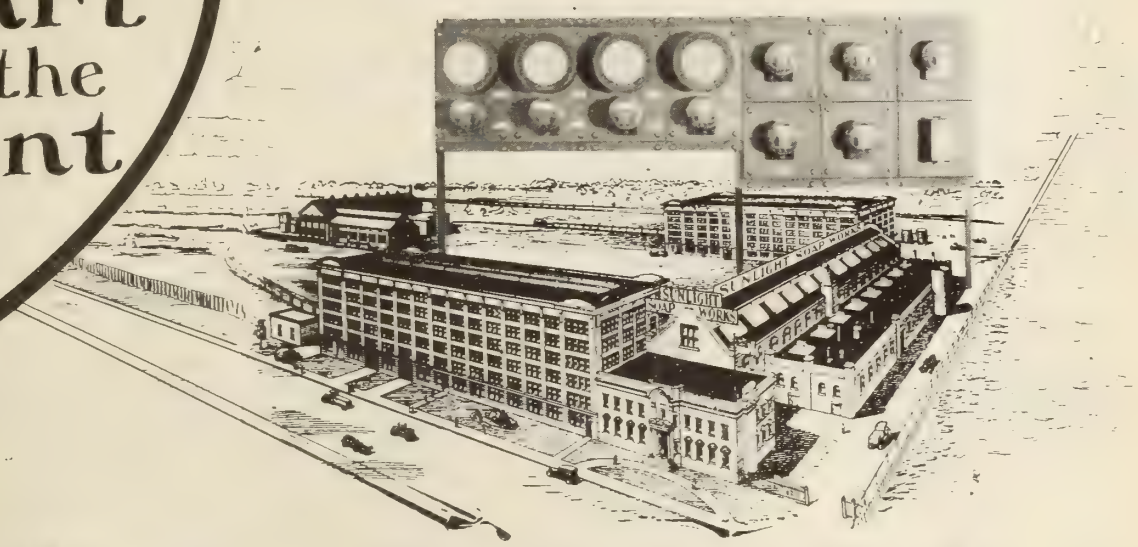
Republic

FLOW METERS

The Heart of the Plant



Good Results at Sunlight Soap Works

The great advantages of the Republic principle of electrical operation are well illustrated in the power plant of the Sunlight Soap Company, Limited, Toronto. The superintendent and the engineer should know what Republic Flow Meters have accomplished; read what they have to say:

Less Fuel Consumed

October 12th, 1920.

The Republic Flow Meter Co. of Canada, Limited,
145 Wellington St. West,
Toronto.

Dear Sirs,—We wrote you some time ago, shortly after your Meters were installed, advising that we were getting good results. The installation is now complete and we have many good figures to work with.

We have located leakages of steam which it would have been impossible to discover without the use of your Meters.

Our fuel consumption is being reduced daily and we hope by the end of the year to have yet more complete and lasting results.

The Meters paid for themselves the first week they were in operation.

We would be glad to furnish particulars to any of your customers who may require information.

Yours very truly,
LEVER BROTHERS, LIMITED,
(Signed) James Mess,
Works Superintendent.

One Boiler Less Needed

October 1st, 1920.

The Republic Flow Meter Co. of Canada, Limited,
145 Wellington St. West,
Toronto.

Gentlemen,—In reply to yours of the 29th enquiring as to the results we have had from Republic Flow Meters, I beg to state that since we have had the meters in operation I have been enabled to cut one boiler from use, and also by discovering leaks in lines, I have been able to carry over the week ends with one boiler instead of two as formerly.

We have been able to make great progress with the conservation of fuel by the application of the meters, and I am convinced that a plant without them cannot be economically run.

I shall be glad to show any person you may refer to me the charts, and prove to them the indispensable value of Flow Meters.

Yours truly,
LEVER BROTHERS, LIMITED,
(Signed) Wm. S. Ball,
Power Engineer.

The departmental lines are all metered, making possible a systematic distribution of steam costs. **Flexibility plus accuracy** is briefly the result of electrical operation. It means that Republic Flow Meters will conform to your plant conditions—it means that you can rely on the indications of the reading instruments. **Write for complete information of the benefits of the Republic Flow Meters in your plant.**

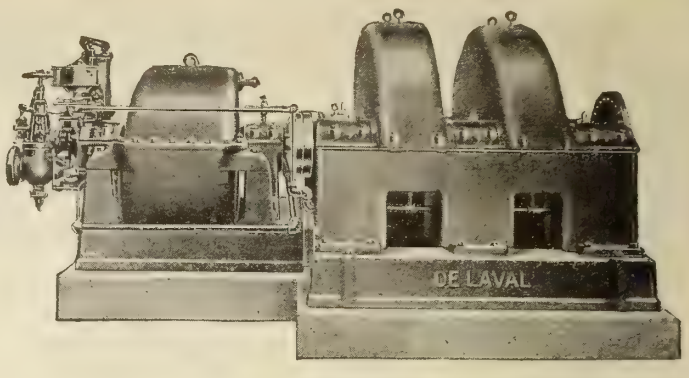
DRIVE YOUR MACHINERY WITH DE LAVAL GEARED STEAM TURBINES



The De Laval Double-Helical Gear makes a highly efficient turbine drive possible and is not a new or experimental development, as many De Laval geared turbines have been in use for more than 25 years.

They are produced in a shop devoted exclusively to precision manufacture on a limit-gage, interchangeable basis. Conservative tooth pressures and velocities are adhered to in their design, which, with the best materials and workmanship, results in smooth, quiet running and long life.

Regardless of what you require power for, whether it be driving ships' propellers, steel mills, paper mills, centrifugal pumps and blowers, electrical machinery, or mill shafting, the De Laval turbine can be adapted to show the most economical results.

State conditions fully and our engineers will submit their advice and suggestions

Ask for Bulletin N-100

Cutting Out Unnecessary Costs

The efficiency of a plant is determined to a very large extent by the dependability of its valve equipment.

If valves break down before other items of equipment an injustice is done to the entire plant, because valves should last as long as good plant equipment.

Good Valves Do.

JENKINS VALVES

are good Valves and the Diamond Trade Mark (cast upon the body) assures continued operation —even where the conditions of usage are most severe.

Their 56 years' service record guarantees that.

The time, labor and expense involved in "shut-downs" for repairs and replacements are entirely eliminated in plants equipped with Genuine Jenkins Valves.

TRADE JENKINS MARK

and satisfy yourself of the many advantageous features embodied in

LUNKENHEIMER "FERRENEWO" VALVES

The body is made of a Ferrous Composition specially alloyed for these valves.

Note the **seat ring** and **disc,**—both of which are made of Lunkenheimer "Valve-nickel," a material having exceptional wear-resisting qualities; the regrindable seating surfaces, the renewability of all parts, including the **seat ring** and **disc;** the full areas through the body; union bonnet; special composition stem, which insures long life to the stem threads; deep stuffing box, etc. These features combined with Lunkenheimer "quality" materials and workmanship make the "FERRENEWO" **the** valve of exceptional merit. Globe, Angle and Cross, and Horizontal and Angle Check Patterns, for working steam pressures up to 150 pounds.

Your local dealer can furnish them; if not, write us. Write for descriptive Booklet No. 576-DC.

Steel Plate Work

We have made a success of building Steel Plate Work by specializing in it. The recent additions to our boiler shops, with the installation of new and most modern equipment, have put us in a better position than ever to handle this sort of work promptly and efficiently.

We use the best material only, build right up to specifications, and turn out this work in a modern shop by modern methods.

The name WATEROUS on your Steel Plate Work is your guarantee that it is built upon all the experience that the past can contribute to the needs of the present.

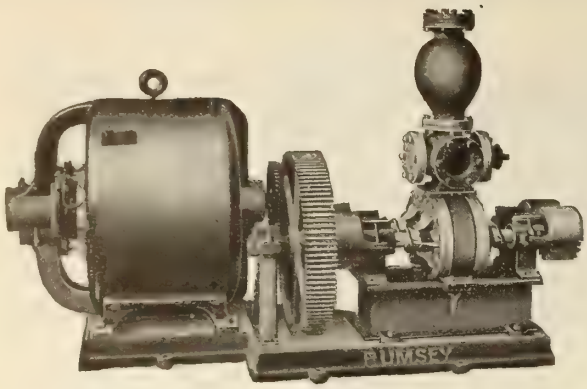
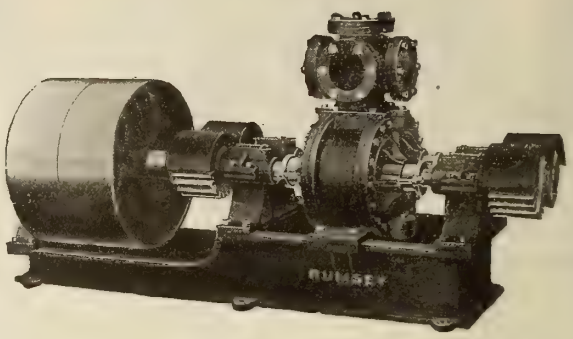
POWER HOUSE. November 5, 1920. Vol. XIII., No. 21 Published semi-monthly at 143-153 University Ave., Toronto, Canada. Subscription price in Canada, $2; in United States, $2.50. Entered as second-class matter at the Post Office Department, Ottawa, Canada. Entered as second-class matter July 1, 1912, at the Post Office at Buffalo, under the Act of March 3rd, 1879.



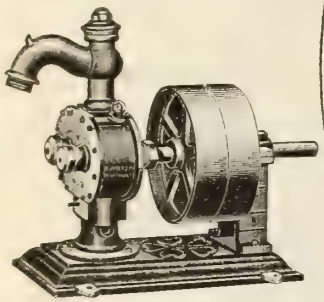
Rumsey Electric Rotary Fire Pump. Designed for general service as well as fire duty. For fire service, 100 pounds pressure is recommended and for general service 75 pounds.



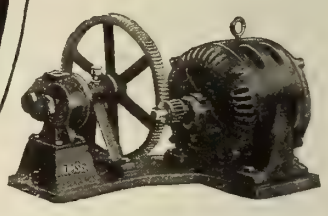
Rumsey Power Rotary Force Pump. Designed for water supply, oils or special liquids for elevations up to 170 feet and pressures up to 75 pounds. A moderately priced pump of large capacity.

RUMSEY ROTARY PUMPS

SENECA FALLS, NEW YORK



Rumsey Rotary Power Force Pump. An inexpensive pump of large capacity in great demand in industrial plants for elevations up to 80 feet. For handling water, oil, paint, varnish or special liquids.



Rumsey Rotary Power Force Pump. A light duty machine designed for returning oil to reservoir from drip pan, also for pumping lubricants for cutting tools, lathes, or other light work where a small pump is required.

Sectional View of Heavy Service Rotary Pump, showing the arrangement of the packing strips with which the toes of the cams are provided.

For general water supply, pumping to sprinkling systems, handling special liquids and for fire protection in mills and industrial plants.

The compactness and convenience of Rumsey Rotary Pumps, their large capacity and low cost make them preferred for all kinds of general pumping. Rumsey Hand and Rotary Force Pumps will handle almost any liquid that will flow—water, oil, paint, varnish, gasoline, grease, tar, ink, extracts, sizes, soaps, chemicals, and commercial liquids of all kinds—liquids of a gritty nature and those corrosive to iron or bronze being excepted.

Is there anything further you would like to know about Rumsey Pumps? Full information gladly furnished by

Above picture shows a practical application of a Bowser 6-F Oil Filtering and Circulating System. It can be used with engines and other machinery where the filtration of dirty oil is essential.

Write for our Booklet on Oil Filtration.

CONSERVATION OF OIL

The consumption of mineral oil products is increasing faster than the production. Consequently engineers are beginning to realize how important and necessary it is to conserve these oils.

A Bowser Oil Filtration System will assist you in doing this.

By filtering oil with a Bowser System it can be used over and over again---or indefinitely. The installation of a Bowser Complete Oil Filtering and Circulating System generally results in a saving of over 50 per cent. on your oil bill.

New Truths and Old Fallacies

Fusibility of Alloys—*Continued*

The best bearing metal may come to grief through mechanical defects, which no babbitt could withstand, or by reason of faulty lubrication, as a grease that is too heavy for a light-running bearing, or an oil too thin for a heavy bearing, will invariably cause heating.

A highly fusible alloy rarely, if ever, gives timely warning before running out, whereas a Magnolia-lined bearing heats so slowly that it permits of either shutting down or cooling off the bearing, while running, without injury to shaft or bearing, and we shall recite cases where entire lack of lubrication has done no harm.

Tin is not the only metal that lowers the melting point of an alloy.

It is most natural to suppose that the melting point of a lead-antimony mixture would not be lower than lead, but that the addition of antimony would even make it higher. The eutectic of this series is 87 per cent. lead and 13 per cent. antimony and the melting point is 447° Fahrenheit, or 212° Fahrenheit less than the mean of the two metals.

It is a common practice to guarantee the melting point of babbit metals to be 600° Fahrenheit, and over, and to view this practice from a charitable standpoint, this guarantee is doubtless given because it is taken for granted that such ought to be the melting point. It is quite evident that the guarantors are not hampered by facts and have no definite knowledge upon which to base their assertions, but they run no risk of detection as buyers are just as much in the dark.

We have a Die-Casting Catalogue of recent date in which is given the melting point of their Genuine Babbitt as 810° Fahrenheit. We believe these figures were obtained from a college laboratory, which gives absolution from intentional misrepresentation, as it is highly improbable that such a wonderful alloy exists, but like many other babbitt manufacturers, they don't know any better.

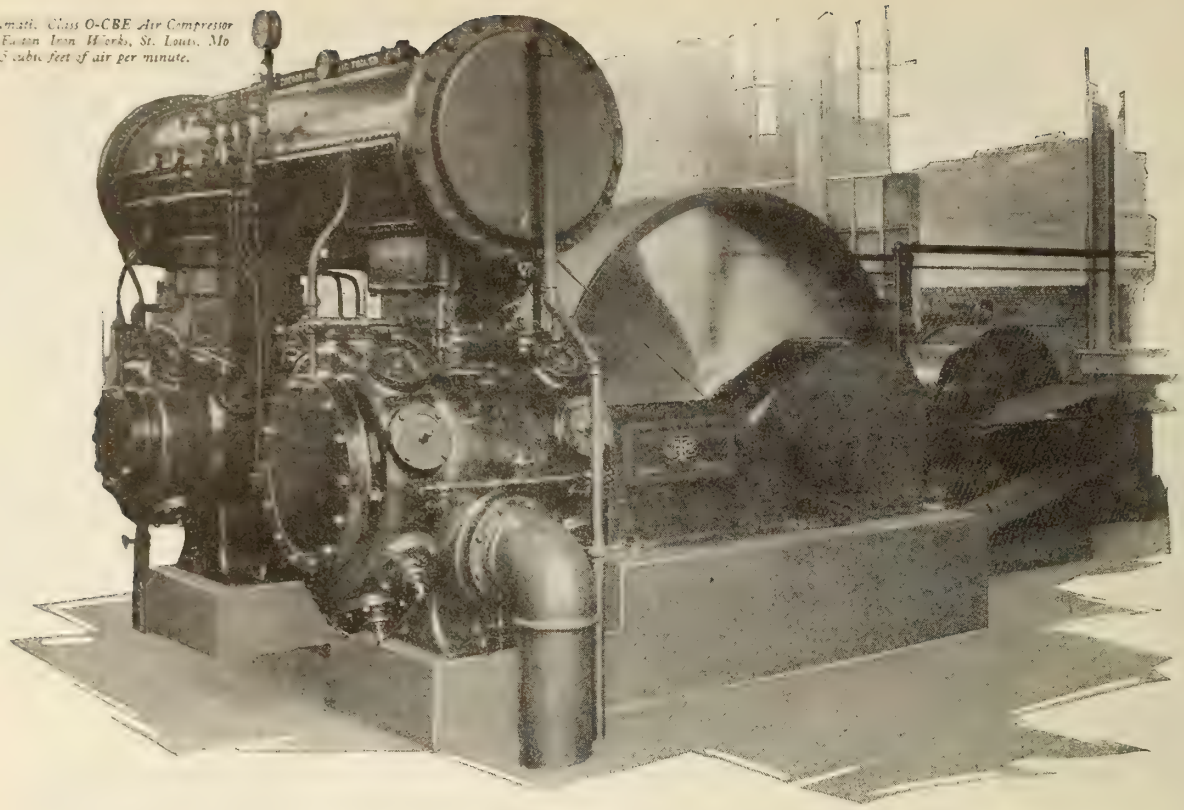
P&C CO



Chicago Pneumatic Class O-CBE Air Compressor motor-driven by Easton Iron Works, St. Louis, Mo Capacity 1145 cubic feet of air per minute.

Is your air compressor sometimes a vacuum pump?

IT IS when the inlet is *choked* in connection with the unloading mechanism.

Choking the suction of an air compressor at no load forms a partial vacuum and *wastes power.*

Contrast this with the operating principle of a Chicago Pneumatic Air Compressor. At no load the valves are automatically held open, permitting free air *without vacuum*—gaining a distinct power-saving over compressors using the choked intake system of unloading.

Standardize with Chicago Pneumatics—"the Compressor with the Simplate Valve." Ask for Bulletin 400.

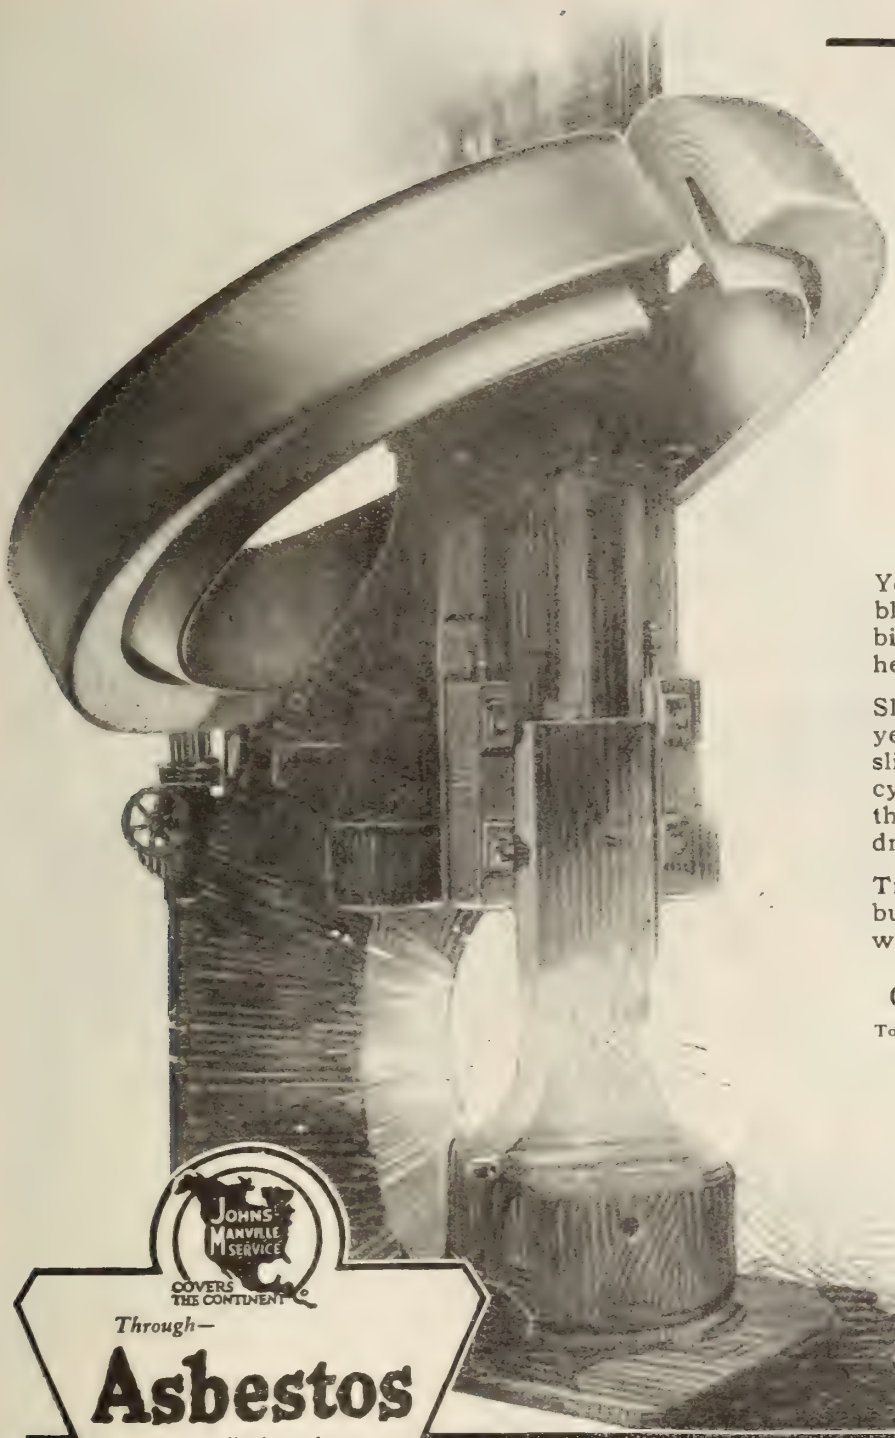
The blow of a giant —or the touch of a baby



DULL, heavy thuds that send the white sparks flying—that beat the unwilling metal into useful forms. Swift, gentle taps that finish off the work.

The steam hammer is a marvel of responsive obedience to those who treat it properly. Keep it oiled, keep it clean and pack it right.

You can't expect instant response on light blows or full force on heavy ones if you bind the rod with inert packing, jammed and held steam-tight by powerful gland bolts.

Slip in a set of Sea Rings, they can't bind yet their pliant lips act instantly to stop the slightest loss of steam. The higher the cylinder pressure, the tighter they pack, but they ease off the moment the pressure drops, and never cause unnecessary friction.

Try Sea Rings, not only on steam hammers, but on pumps, engines, air compressors or wherever a rod or plunger has to be packed.

Built to Lower Industrial Costs—This Steam Hose

Goodyear Steam Hose definitely lowers industrial costs:

—by giving longer service.

—by doing away with the nuisance of *heated* wire-winding, and *bent* wire-winding.

—by enabling you to cut steam hose to any desired length.

—by preventing blistering and bursting from unequal expansion.

These things Goodyear Steam Hose does because Goodyear has developed a steam hose so strong and tough that wire winding is unnecessary.

Goodyear would not have developed this new type of steam hose had Goodyear been content to build industrial hose in the same old way.

But Goodyear investigation and research into hose failings and hose possibilities revealed whole new fields of endeavor. The result is a complete line of industrial hose of super-serviceability and unusual economy.

Goodyear builds steam, air-drill, water, suction, fire, and other types of industrial hose. The expense of hose in your plant can be decreased and the amount of work done increased by a Goodyear analysis of your hose problems. A trained Goodyear man will call on you without obligation. Phone, wire or write the nearest branch, or Goodyear Mechanical Goods Service Station.

ICE MACHINERY SUPERIOR SINCE 1882
BRANCHES IN ALL PRINCIPAL CITIES

There is a FRICK Machine for every refrigerating purpose — all types: Vertical — Horizontal — Absorption.

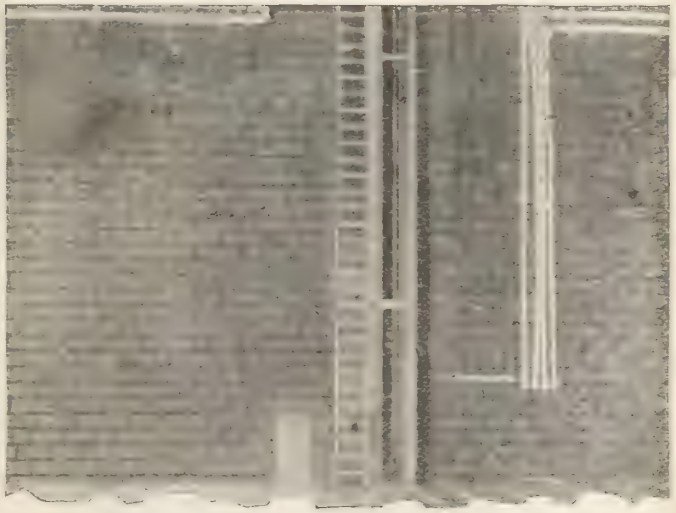
Canadian Representative: FRICK Ice and Refrigeration Co., Montreal

Next Summer's Prices for this Winter's Ice

THE economy of ice storage has been conclusively demonstrated. Storage of slack season production means reduced cost because of continuous operation. Furthermore, it insures an ample hot weather supply and increases plant capacity without additional machines.

The important consideration is the cost of refrigerating the storage room, and that depends largely on the quality of insulation used. With Nonpareil Corkboard in sufficient thickness, very little refrigeration will be required; operating cost will be low, making the storage profitable.

An ice storage should not require re-insulation every few years. And it won't if Nonpareil Corkboard is used. For not only is Nonpareil Corkboard most efficient in retarding the inflow of heat, but it is non-absorbent and non-decaying. Properly installed, it should last as long as the building.



Peoples Ice Company, Wichita Falls, Tex. Insulated with Nonpareil Corkboard, mastic finish

The Company's engineers will gladly furnish you with reliable data on the construction and economy of an ice storage for your plant. If interested, write for information and a copy of the book, "Nonpareil Corkboard Insulation." No charge or obligation for either.

NONPAREIL CORKBOARD INSULATION

For Ice Storage Rooms

QUALITY YORK SERVICE

York Uniflow Engines for Ice Making and Refrigerating Plants

One of the most important considerations in an Ice Making or Refrigerating Plant is the type of prime mover. An economical ice plant should have a dependable motive power, and one which will maintain a reasonable economy when called upon to operate over a range of from ¼ to 1¼ times the normal load.

It is well known among refrigerating engineers that the best compressor economy is obtained when evaporating pressures are carried as high, and condensing pressures as low, as possible. Even well balanced plants are forced to meet extreme seasonal conditions, with evaporating pressures varying from 20 to 30 pounds and condensing pressures from 85 to 225 pounds. These pressure variations and seasonal requirements of the Trade impose load factors of corresponding variation on the engine operating the compressor.

The Uniflow Steam Engine presents itself as the best solution of this difficulty

High Duty means Low Cost

Make this simple comparison: Balance the guaranteed saving of the Jones "AC" Stoker against the interest on investment necessary for a complete installation. This is the true test of stoker worth.

The first cost of any stoker is a fixed amount, so that it is the many factors covered by the one word "saving" that determine the real cost of a stoker—saving in fuel, in labor, and as a result of reduced maintenance cost—these are the all-important items.

Hundreds of power users have found Jones Stokers a highly profitable investment as a result of unequaled ability to—

Save coal—by correct application of the Jones Under-Feed principle, which insures greater boiler capacity, ability to meet violent load fluctuations, and effective operation with every grade of coal. Save labor—by automatically controlling the supply of fuel and air, and by practically eliminating clinker trouble.

Reduce maintenance cost—as a result of extreme simplicity, rugged construction, and general accessibility.

The Jones "A-C" Stoker is manufactured by an old-established Canadian Stoker Manufacturer, newly reorganized to render a greater engineering service to Canadian power users. Write for extensive catalogs.

The Under-Feed Stoker Company of Canada, Ltd.
81 VICTORIA ST., TORONTO

Pays for Itself-then Pays Dividends

THE STOWE STOKER

EMPLOYING MECHANICAL DRAFT

Its fundamental principle is a conveyor feed, positive in action from coal-hopper to ash-pit.

The Incline Results in Strong Ignition Temperatures

The Stowe Stoker is the *only* conveyor feed built on a decided incline. Every engineer can readily understand the underlying principles of such an incline, and appreciate its great value in producing strong ignition temperatures.

This advantage is particularly apparent in the burning of coals that are hard to light up, because of high moisture or low volatile, such as lignite, coke breeze, river anthracite, and the semi-bituminous coals.

The incline of the Stowe Stoker, because of the (resulting) high bridge wall, vertical flame travel and good furnace arrangement generally, produces very high temperatures at the front of the furnace, causing the incoming coal to ignite with great rapidity and intensity.

Coal will burn only as fast as it can be made to ignite, and *all* stokers have at times their limitations in this one particular. The rate of ignition in the Stowe Stoker, however, *exceeds that of all others,* with the added advantage of a positive, uninterrupted action from coal-hopper to ash-pit.

The Power Plant of a Flour and Salt Mill

The Western Canada Flour Mill Co. at Goderich Operates a Combined Salt and Flour Mill—The Steam After Driving the Mill, Goes to the Salt Plant to Evaporate the Brine.

By T. H. FENNER

WHILE everyone is aware that flour and salt are two very necessary ingredients in making bread, it is not generally known that they can be manufactured together in the same mill. Of course it would not always be feasible, as it is in the case we are about to describe. Here the flour mill happens to be located over a bed of brine, and the same steam power is used to drive the elevator, run the flour mill, pump the brine, and make the salt. In fact the use of the steam in this plant recalls the use of the pig in the packing plant. Nothing is lost but the squeal, in the case of the pig. The steam, possessing no squeal, cannot lose it, and everything else is fully utilized.

The mill in question is that of the Western Canada Flour Mills Co., situated at Goderich, Ont., and it is an interesting plant from the point of view of the power plant engineer. We do not mean by this that it is a plant replete with all the most modern devices and instruments to make for efficiency, because it is not that. We do mean to say, however, that for a plant that suffers from perhaps a little more than the usual drawbacks it is a model of good management and efficiency. The good results obtained from the plant are due of course to the utilization of the steam in the salt manufacture, but it is due to the care bestowed on the upkeep that all the steam that passes through the engines is delivered to the salt plant. In other words, there are no leaks.

Description of Plant

The boiler room contains six boilers, five of which are Heine water tubes and one Babcock & Wilcox water-tube. These boilers are of various ages, the last to be installed being the B. & W. unit, which is about eleven years old. Two of the Heine boilers are fifteen years old, and the other three are twenty years old. The three latter have a combined heating surface of 3,051 square feet, the other two having 2,758 square feet, the B. & W. unit being of 3,140 square feet. This gives a total heating surface of 8,949 square feet, or 895 rated horsepower. The working pressure is of course governed by that allowed the oldest boilers, and the safety valves are set at 130 pounds. Hand firing is in use, and the coal has to be wheeled into the boiler room by a horse and cart, ashes being removed in the same way. The coal is brought into the yard from the steamers by the belt conveyor shown in the illustration and dumped on the pile. Formerly the coal was shoveled onto the carts to be taken to the boiler room, but a better method is now in vogue. A small donkey engine has been rigged close to the pile, and from this drags or scoops are operated, which pull the coal from the pile on to the cart in cartload lots. The horse that runs the coal cart has had the lesson of efficiency instilled in him as he absolutely refuses to do any other job than this one. He can reach the boiler room from the coal pile, back in, unload, and come out with the minimum number of steps, and so much is he engrossed in the power plant that he will allow no one but a power plant man to come near him. Mr. Taylor, the chief engineer, claims that a card taken from him would show very high power development on a small consumption (oats we presume).

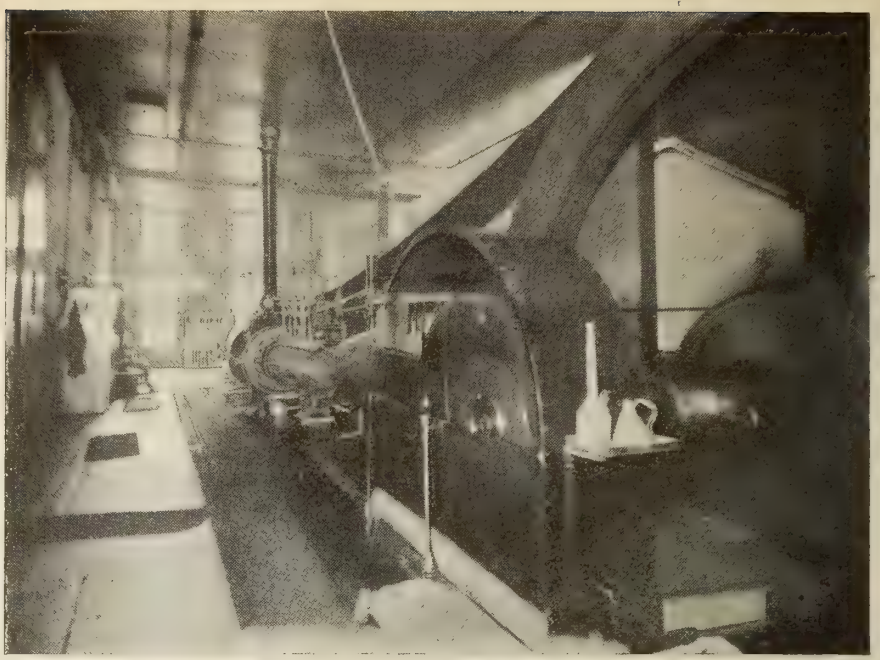
The only automatic appliances in the boiler room consist of Gelison draught gauges and a McDonough feed regulator on one boiler. There is a McDonough damper regulator fitted controlling the stack damper, and this has proved a very useful auxiliary. These boilers are always being worked up to and above rating, and under the hand-

THE GRAIN ELEVATOR COAL CONVEYOR AND COAL PILE.

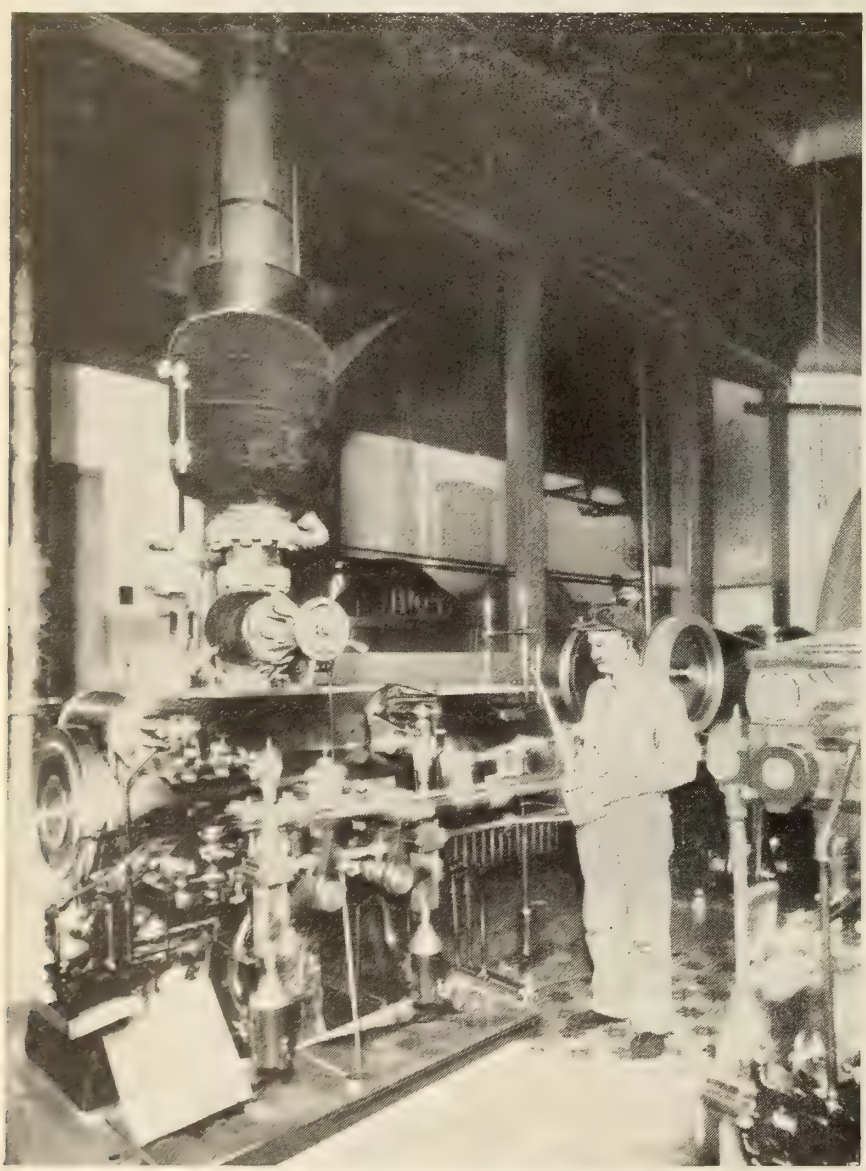
firing conditions considerable lifting of safety valves took place, with the usual amount of loss attendant on safety-valve blowing. The installation of the damper regulator has done away with this, and the only occasions on which the valves lift now are at the daily inspection.

The Engines

The mill power plant proper contains two engines, one of the Corliss type and one cross compound with Brown valve gear. The Corliss engine is interesting in that it has a history and is of ancient lineage. It was installed in the mill about the year 1874 by the same man who installed the famous Corliss engine at the Centennial Exposition in the United States. It ran without a hitch until the year 1913, when the strap on the connecting rod end broke. This resulted in a smashed-up cylinder, and led to the replacement of this part of the engine. A new cylinder 26 inches diameter was fitted, together with new valve gear, and the opportunity was taken to replace the old single eccentric arrangement for all valves with the more modern double eccentric, one for the steam and one for the exhaust valves. The engine as it stands to-day is 26 inches by 60 inches stroke, with a speed of 65 revolutions per minute. The original guide frame, connecting rod, flywheel and journal are still in commission. The flywheel is 22 feet 4 inches in diameter, with a 36-inch face. No doubt, due to this heavy wheel and efficient governor regulation, the speed of this engine is remarkably regular, a highly important feature of a flour mill engine.



THE OLD CORLISS ENGINE.



THE BROWN ENGINE. NOTE EXTRA LARGE PIPE ABOVE SEPARATOR.

In the same engine room there is a cross compound engine 15 inches by 24 inches by 36-inch stroke, fitted with Brown valve gear and built by the now defunct Polson Iron Works in 1910. This engine as originally built was designed for 88 revolutions per minute. In the year 1913 the demand for power rose from 750 to 950 horsepower, and to get the increase this compound engine was increased from 88 to 98 r.p.m. In this connection a difficulty arose, which was overcome in an ingenious manner by Mr. Taylor, the chief engineer. This gentleman has the very good habit of putting an indicator on all his engines at very frequent intervals, a habit which has much to do with his success. Any change in valve operation due to ordinary wear and tear which develops in working is thus speedily discovered and corrected. After increasing the speed of the engine the steam line of the indicator diagram showed a drop from the point of stroke commencement, such as would be shown by insufficient port opening. Increasing the lead did not overcome the trouble, and it was necessary to go further afield. Mr. Taylor then applied his indicator to the steam chest itself and speedily discovered his trouble. The increase of speed had caused a greater demand than the steam pipe had capacity for, or in other words the greater velocity of the steam led to a decrease in pressure. In order to correct this the larger diameter pipe which is seen in the photograph on the steam

THE BRINE PUMP SHOWING THE OVERHEAD GEAR USED BY WELL SINKERS.

pipe of the engine was added, with very good results. The cards are reproduced here showing the alteration from conditions before fitting the large pipe, or receiver, and after. The improvement is very noticeable.

There is a small electric lighting unit also in this engine room, an Ideal type 9 by 12 inch, running at 300 r.p.m., developing 50 horsepower.

The exhaust steam from all these engines is run to the salt plants, which will be described later.

The Grain Elevator Engine

The huge grain elevator is run by a cross compound Goldie & McCulloch engine 15 inches by 28 inches by 30 inches, running at 120 revolutions per minute, and developing 350 h.p. This engine is condensing, and drives through a belt a 220 kw. 60-cycle generator, running at 600 r.p.m., which supplies current to the motors in the elevator. The grain is taken from the ship's hold and elevated into a marine leg, the engine operating the grain shovels being a 10-inch by 10 inch at 300 revolutions per minute. From the marine leg the grain is conveyed through a tunnel and into the elevator bins by belt conveyors, and stored there until required in the mill.

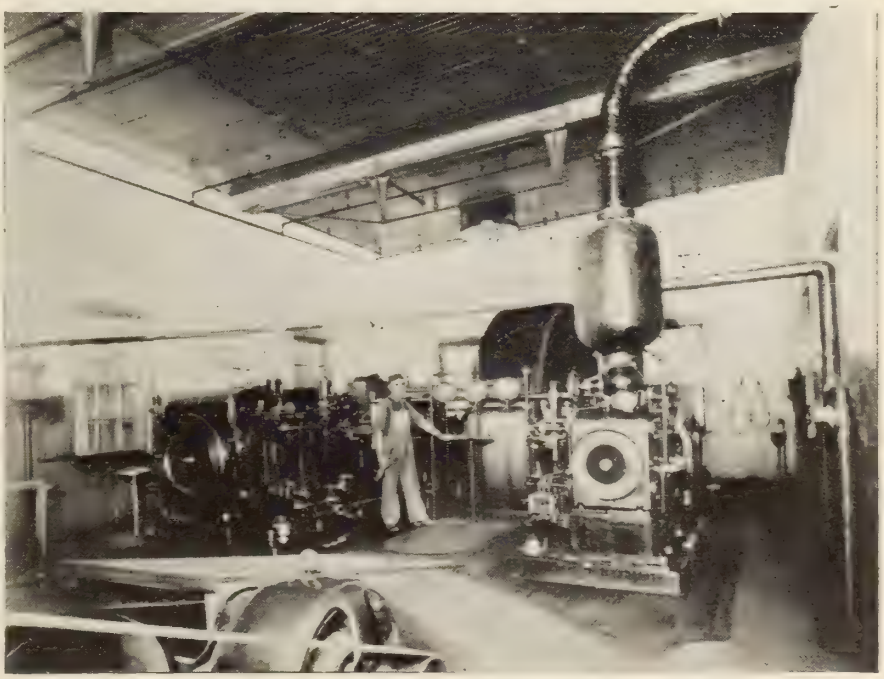
In addition to these units there is a high-speed engine 11 by 12 inches, running at 300 revolutions per minute, for operating the coal conveyor, and the small engines operating the brine pumps. There is also a 2-cylinder fire pump and a Westinghouse air compressor which supplies compressed air for the dry sprinkler system. This list covers all the units, which total 2,015 horsepower. Of course they do not all run at once.

The Operating Features

The principal units are those operating the mill proper, that is the 26 by 60 inch Corliss, and the 15 by 24 by 36 cross compound. These engines run continuously from early Monday morning till late Saturday night, and the only chance for repairs is on Sunday. The boiler plant is running continuously, and it is only about once a year that any opportunity arises for a shut-down, and this does not occur at regular intervals. One boiler is washed out as well as can be managed every Sunday, the turbine being passed through the tubes when necessary. The boilers are blown down regularly and a boiler composition is used. The feed water is taken from a 750 h.p. Cochrane heater, and in order to help this out the water is first passed through the tanks which contain coils. These coils are used to pass the exhaust steam from the feed pumps themselves, thus preheating the water before it goes into the heater. In this way the lack of adequate space in the heater itself is made up and the feed pump exhaust fully utilized. It was particularly noticed by the writer while passing through the plant that in no place was there any sign of a steam leak, and when the continuous operation is considered this speaks very highly for the care bestowed on the plant.

Owing to the two engines here mentioned carrying the brunt of the load, all the fuel burnt is charged against them. Previous to 1913 the plant had not been in particularly good condition and the consumption of fuel for the years 1911 and 1912 worked out at 4.1 and 4.07 pounds per i.h.p. per hour.

In 1913 Mr. Taylor, the present chief engineer, took charge, and immediately went to work to pull things up. In this he was materially assisted by what have been thought an unmitigated calamity, to wit, the breakdown of the Corliss engine. This gave an opportunity for a



THE ELEVATOR POWER PLANT.

thorough overhaul, with the result that the consumption per i.h.p. per hour came down from 4.07 to 2.44 pounds. This was a noteworthy saving and it may be said here was not on paper only but showed very materially on the fuel bills of the mill. The average consumption for the years 1913 to 1919 conclusive, which covers the period of the war, with its attendant fuel troubles, worked out to 2.85 pounds coal per i.h.p. per hour. This result, with the type of engines used and a comparatively low boiler efficiency due to low setting of boilers and hand firing conditions, is highly commendable, even if the exhaust steam was lost. However, in this plant the exhaust steam has a very important part to play in the making of a by-product—salt.

The boilers are fitted with rocking grates, which were adopted after evaporation tests had been run to determine the performance with straight grates and rocking grates. This was occasioned by the difference in the grade of coal being received. We reproduce here the evaporation tests and their results. They showed enough advantage with rocking grate equipment to warrant the adoption of this apparatus. These bars were supplied by the Galt Foundry Company. The original bars were of the herringbone type.

It will be seen that the efficiency reached, 66 per cent., is very satisfactory under the conditions of operation. It is higher than the average hand-fired power plant, which does not often reach 60 per cent. With stoker installations, of course, a much higher efficiency can be maintained, around 75 per cent. being not unusual.

The Salt Plant

We have spoken about the salt plant and now will describe it in detail. First of all it may be said that there are considerable brine deposits around all that portion of the country, from Windsor to Goderich. The brine in the case of the Goderich mill is encountered at a depth of 1,200 feet, and is obtained by sinking a well and installing a deep well pump. In the plant at Goderich there are two wells, and the pumps used are of the ordinary clock valve type, operated by a walking beam, which is driven from a pulley by a crank and connecting rod. The pulley is belt-driven from a small horizontal engine.

The exhaust steam from the engine is utilized in part to pre-heat the brine before it goes to the grainer or evaporators. It will be of interest to readers to know the composition of the brine, and we herewith give the chemical analysis. The chief constituents are of course water and sodium chloride, the latter of course being common salt. The percentage of water is 73.054, and common salt 25.054. The remaining constituents are slight traces of calcium sulphate, calcium chloride, and magnesium chloride. The density of this brine may be better appreciated perhaps by comparing it to sea water. This contains only 5 ounces of solid matter to one gallon, or in other words about 3 per cent.

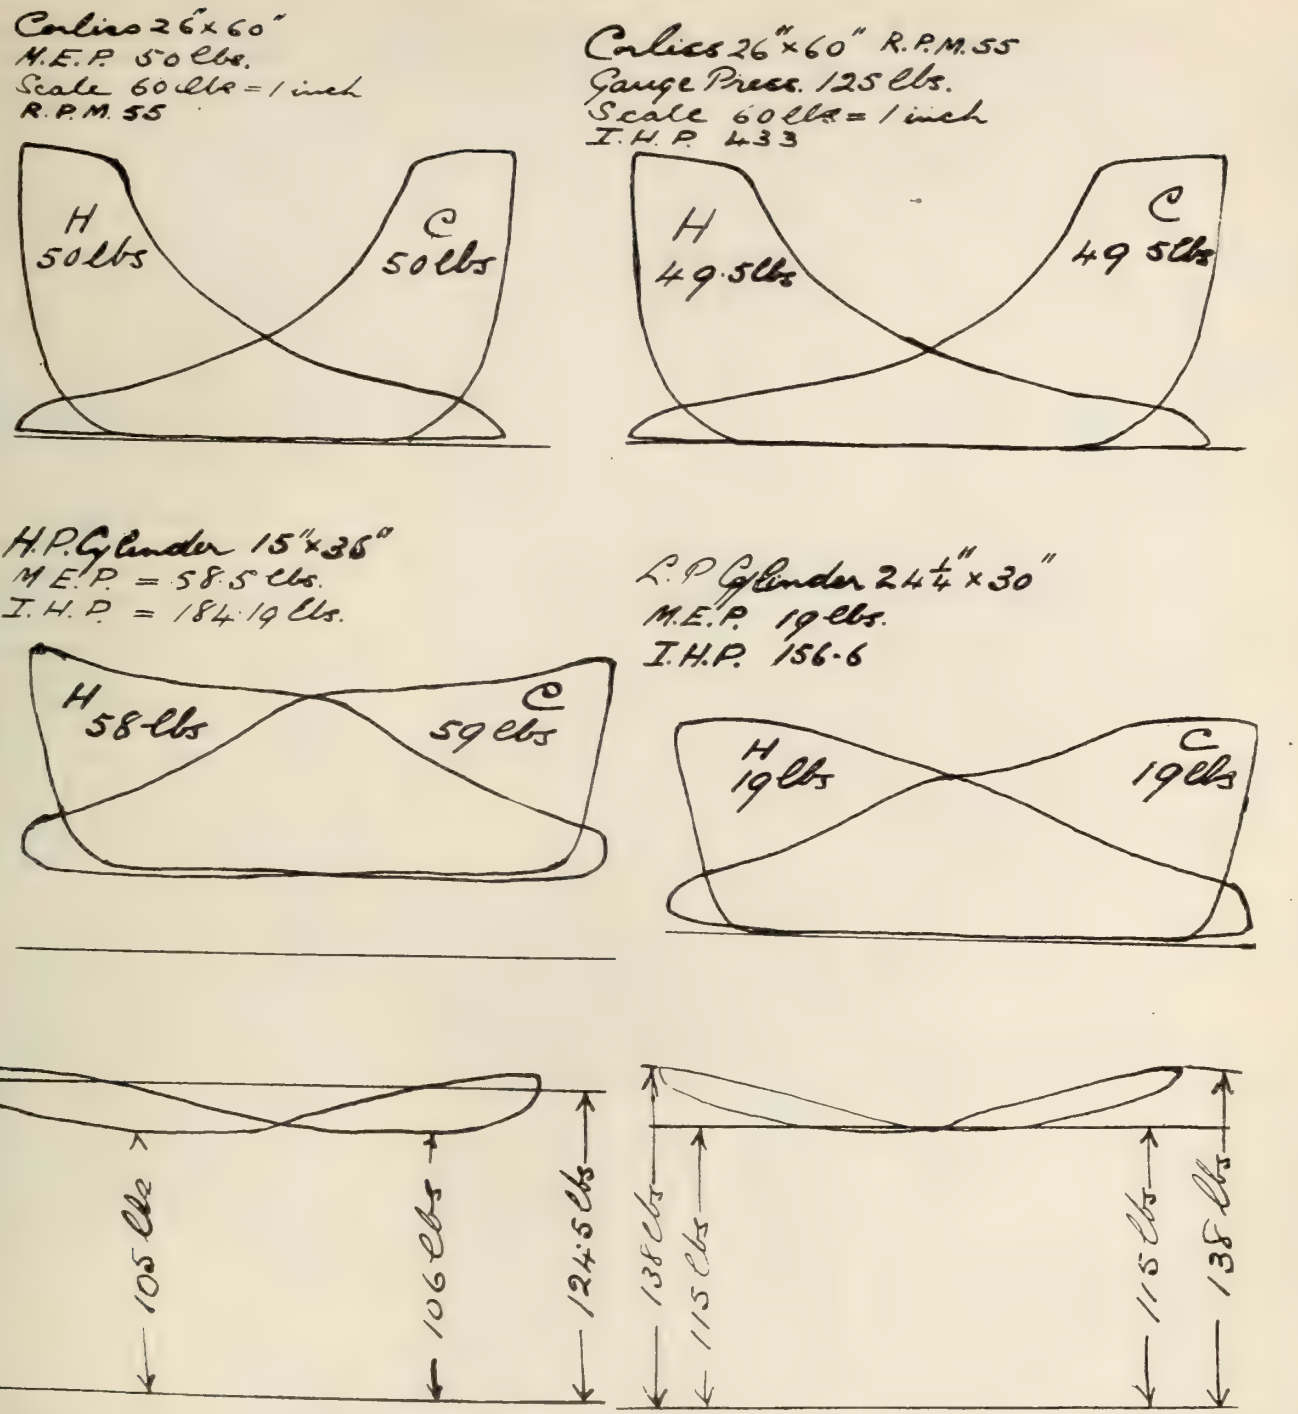
The salt is recovered from the brine by a simple process of evaporation, and there are four of these evaporators or grainers as they are called. Three of them are of the same type, and one of more modern construction. The three are simply double-bottomed steel pans, one about 126 feet long by 20 feet wide, the other two being the same length but narrower. The exhaust steam is passed through coils in the lower pan, being admitted at about ½ pound pressure above atmosphere. The action is of course to evaporate the water and leave the solid residue behind. This process can be clearly seen, the crystals gradually forming on the surface of the water, and after attaining a certain density sinking to the bottom of the tank. A peculiar feature of this evaporating process is that the process goes much better if the water is kept slightly agitated. If the water is perfectly still a slight scum forms over the surface, and this has the effect of retarding the separating of the steam from the water. It is analogous to what takes place in a dirty boiler. The vibration required is in the case of the three large steel pan grainers provided by the natural vibration of the building which contains them. The salt is recovered from these grainers by hand, the men using rakes with a hinged blade. This blade doubles back on the hinge as the rake is pushed forward, and straightens out when pulled back, bringing the salt with it.

The smallest grainer is of 840 square feet area and is different in construction and operation to the other three. It is built of concrete, and the steam coils are laid directly in the brine. A peculiarity of steel pipe was discovered in this connection, in that it was found to be porous, while iron pipe is not. With steel pipe the brine found its way into the pipe

Comparative efficiency tests made on 5 water tube boilers at the plant of the Western Canada Flour Mills, Goderich. Object of tests: To determine what advantage could be obtained by the use of the McNaughton rocking grates. The results herewith given are self-explanatory.

Test No. 1, with herringbone grates. Test No. 2, with rocking grates:

		Test No. 1	Test No. 2
Total Quantities	Date of test	5-3-15	18-5-15
	Duration of test	8 hours	8 hours
	Kind of coal used, oil test	Slack	Slack
	Weight of coal used, oil test	24.800 lbs.	22.800 lbs.
	Weight of dry coal used, oil test	23.312 lbs.	21.432 lbs.
	Calorific value of coal used, oil test (given as 13.800 B.t.u.)	13.800 B.t.u.	13.800 B.t.u.
	Moisture in coal used, oil test	6%	6%
	Total ash	1937 lbs.	1500 lbs.
	Percentage of ash in dry coal consumed	9%	7.5%
	Total combustible	21.375 lbs.	19.932 lbs.
	Total water fed to boilers (actual conditions)	151.372 lbs.	167.218 lbs.
	Equivalent evaporation from and at 212°	184.825 lbs.	202.000 lbs.
Hourly Quantities	Weight of coal as fired per hour	3100 lbs.	2850 lbs.
	Weight of dry coal as fired per hour	2914 lbs.	2679 lbs.
	Weight of water evaporated per hour (actual conditions)	18.921 lbs.	20.902 lbs.
	Equivalent evaporation from and at 212°	23.103 lbs.	25.250 lbs.
	Coal burned per sq. foot of grate per hour	22.3 lbs.	22 lbs.
Boilers and Furnaces	Type of boilers used on test	Heine	Heine
	Number of boilers used on test	5	5
	Heating surface of boilers	6000 sq. ft.	6000 s. ft.
	Horse power of boilers	600 h.p.	600 h.p.
	Horse power developed on test	670 h.p.	732 h.p.
	Type of grates	Herringbone	McNaughton
	Area	138 sq. ft.	130 sq. ft.
Average Pressures and Temperatures	Steam pressure by gauge	125 lbs.	125 lbs.
	Draft at furnace	.28	.28
	Draft at stack	.75	.75
	Temperature of water fed to boilers	42°	55°
	Temperature of flue gas	540°	550°
Economic Results	Water evaporated per lb. of coal (actual conditions)	6.1 lbs.	7.3 lbs.
	Equivalent evaporation per lb. of coal from and at 212°	7.45 lbs.	8.86 lbs.
	Equivalent evaporation per lb. of dry coal from and at 212°	7.92 lbs.	9.42 lbs.
	Equivalent evaporation per lb. of combustible from and at 212°	8.6 lbs.	10.13 lbs.
	Factor of evaporation	1.221	1.208
Efficiency	Efficiency of boilers and grates (based on dry coal)	55.4%	66%



SOME EXAMPLES OF INDICATOR DIAGRAMS. THE TWO LOWER CARDS ARE THOSE TAKEN FROM THE STEAM CHEST AS DESCRIBED IN THE TEXT.

and was detected by depositing on the interior surface. With iron pipe this does not occur. The operation of this grainer is automatic. Two angle irons laid back to back with a slot between them are arranged at each side of the tank extending the greater part of their length. A T-bar is laid on these each side with its web running between the slots left between the angle irons. Across the tank bars are riveted to these T-irons, and these bars carry a hinged blade or rake. A crosshead is also secured to these T-bars, and a connecting rod drives the crosshead from a pulley and crank. The speed is reduced from the countershaft drive by means of a double reduction gear consisting of worm and wheel and spur and pinion gearing. The action is of course a reciprocating motion of the rakes up and down the tank, and they travel at one end up an inclined wooden apron. When travelling away from this apron the rakes swing back flush with the surface of the salt, but when going to the apron they fall vertical and push the salt ahead of them. They go far enough to push the salt over the edge of the wooden apron, and it falls on to a belt conveyor which carries it away to storage. The movement of the rakes supplies the necessary disturbance of the brine, which is conducive to good evaporation. Small scrapers are suspended from the cross bars which scrape the surface of the coils, much in the manner of the scrapers used in the Grun's economizer. This grainer is entirely automatic and requires no attention beyond occasional maintenance repairs.

The exhaust steam after condensation is of course returned to the feed water and thence to the boilers. In winter of course some of the exhaust steam is required for heating the mill but when any of the isolated engines are running their exhaust can be utilized for this purpose.

With the salt grainers in full evaporation it is possible to evaporate 200 tons of water per twenty-four hours, which corresponds to a production of about 50 tons of salt. The heat available in the

steam is 1147.9 B.t.u. per pound at the salt plant, while the heat of the steam entering the engine is 1189.5 B.t.u. per pound. This shows what a wasteful thing a steam engine is at best.

We have spoken of the continuous operation of this plant. The following are the only accidental stops which have taken place from 1914 to date:

1914.—Short stop due to engineer caught in regulator belt.

1915.—Stop on account of hot rocker arm.

1916.—Part of valve gear breaking.

1919.—Stop due to hot bearing.

1919.—Stop for loose follower bolt.

Two of these stops were unavoidable and the others were caused by negligence on the part of a shift engineer.

There is a regular system of inspection carried out every Sunday, every part of the plant being carefully examined and precautions taken to prevent any breakdown. The results speak for themselves. As we said before, the chief engineer, Mr. Taylor, is a great believer in the use of the indicator, and he keeps after the valve gear of all the engines persistently. Mr. Taylor spent twenty-six seasons as engineer on the Great Lakes, and has many interesting experiences to tell of. He is an engineer from the toes up, and loves his profession. Like most successful engineers he is keen on technical knowledge and encourages his men to obtain it. We are reproducing some of these cards taken during our visit to the plant.

JOINS CONVEYORS CORPORATION

An interesting detail of the change in name of the American Steam Conveyor Corporation to that of "Conveyors Corporation of America," is an addition to the personnel of the Eastern Sales Organization.

Mr. Clarence C. Brinley has been retained as Eastern manager of the trolley carrier department, and will be attached to the New York office, 110 West 40th Street. Mr. Brinley is an engineer of broad experience in elevating and conveying machinery and has a wide acquaintance in engineering and business circles in the East. He has drawn his experience from some of the leading manufacturers and users of handling equipment, having first been connected with C. W. Hunt Co., and coming to the Conveyors Corporation from Gifford-Wood Company. During the war he was conveyor engineer for the Air Nitrates Corporation.

A student and a writer of some ability, Mr. Brinley has made several very valuable contributions to the rather sparse amount of worth-while information about the mechanical handling of bulk materials. He wrote a series of articles on "Handling Machinery in the Power Plant," published in "The Engineering Magazine" (now Industrial Management) in the fall of 1915; two articles on "Bucket Elevators," and several on the "Design and Construction of Retail Coal Pockets," contributed to the "Coal Trade Journal" during the spring and early summer of this year.

Entering the field as a draftsman with C. W. Hunt Co., at the age of eighteen, Mr. Brinley, through persistent application and diligent night study both at home and at Columbia University, rose rapidly to a position of prominence in the world of conveyor engineers. Evidence of his skill may be seen in the form of unloading towers, power plant installations, and coal pockets along the railroad lines and the water front of many sections of this country and abroad.

His wide experience in the design and application of conveying machinery has been rounded out by the supervision of the construction of several important handling machinery installations in various parts of this country and in Latin America, and by three years of successful salesmanship in the Eastern territory.

Mr. Brinley has a wide acquaintance among prominent engineers and successful business men in the East, and has made fast friends of many of his business associates.

ARMSTRONGS AND TURBINES

It will not come as a surprise that such important suppliers of war material and battleships and smaller ships of war as Messrs. W. G. Armstrong, Witworth & Co., should be very seriously taking up the manufacture of water turbines, and indeed laying themselves out to execute contracts for complete hydro-electric plants.

The peace-time requirements of munitions, if indeed we can call the present a time of peace, will naturally not furnish a market for the products of works of the size of Armstrongs. Soon after the armistice a large part of the gun shops at Scotswood, Newcastle-on-Tyne, was converted for the building of locomotives, and a $15,000,000 contract for the Belgian Government is now in course of execution. Again, the armor plate shops at Openshaw, Manchester, have been largely turned to locomotive repair work.

Water turbines will be built in the works of the group in Glasgow, which, with large extensions built about two years ago, are being worked under the title of Armstrongs and Main. The Openshaw works, too, will be called in.

Time will show whether Messrs. Armstrong will manufacture at least a part of their requirements for Canada in Canada itself. Such a step may naturally be expected, and it would undoubtedly be welcomed amongst those who still appreciate high-class workmanship, but at the same time must be on the look out for plant to suit local conditions and requirements.

It is interesting to note that Messrs. Armstrong have gone to Norway for their designs, and have secured them from a firm who have delivered, amongst many others, the following units:

	H.P. of each unit	R.P.M.
A/S Tyssefaldene	5,000	375
Rjukan No. 1 Plant	15,000	250
Do., No. 2 plant	16,400	250
A S Bjolvefossen	.....	375
Vamma Power Co.	12,000	214
Vamma Power Co.	13,000	214
Vamma Power Co.	15,000	214
Herlandsfossen Power Co.	3,500	600
Aarlifos Power Co.	6,000	187.5
A/S Saudefaldene	7,500	375
A/S Saudefaldene	6,700	750
A/S Traelandsfos	8,000	214
A/S Shallenborg	2,750	250

It will, therefore, be seen that the British firm should be fully capable of handling the largest units which may be entrusted to them to manufacture, whether of the "Francis" or "Pelton" type.

BOOK REVIEW

We are in receipt of an interesting book by Mr. E. B. Biggar, former editor of "Canadian Engineer." The volume is entitled "Hydro Electric Development" in Ontario. The subject is dealt with by the author from the point of view of a strong protagonist of public ownership, and in the first chapter he goes back to Biblical times to prove that public ownership is directly commanded by the Creator. In the second chapter he compares the power resources of Canada and the United States. Subsequent chapters deal with the original development of Niagara, and the struggle for control between public and private interests. The account of the early attempts at utilising the power is very interesting. A chapter at the end of the book contains a glowing eulogy of Sir Adam Beck, and gently chides the citizens of London for having turned their backs on the peerless knight at the late elections. Apart from the predilection the author shows against private owners and for public ownership the book is interesting, and the facts contained therein useful even if one has different opinions on the subject. The book is published by the Ryerson Press.

The Packard Electric Company, of Warren, Ohio, have issued a Bulletin on "Metering Transformers" in which are described the weatherproof and switchboard types of single, two and three phase potential and current transformers. The weatherproof, or out-door type of oil-insulated transformer has been developed in compliance with the insistent demand from the central manager who is anxious to avoid the building of a housing to protect the transformers from the weather.

A new warehouse is planned by MacDonald-Crawford, Ltd., at Regina, Sask.

Work has started on the new Garrick Theatre, Winnipeg, by Alexander M. Simpson, contractor. This theatre will be situated at the southwest corner of Garry Street and Ellice Avenue and will cost about $150,000.

Saving Fuel by Controlling Chimney Losses

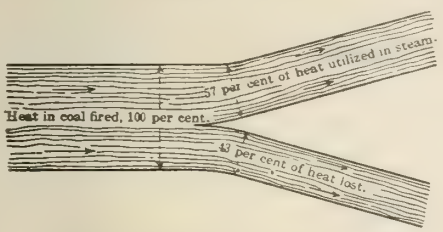
Paper Delivered Before the Fuel Section of the Sixth National Exposition of Chemical Industries, New York—The Author is an Authority on This Subject, and Commands Attention

By F. F. UEHLING.

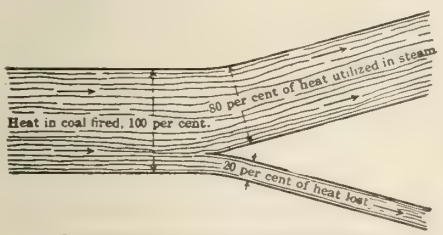
THE subject of fuel economy is today of greater interest to the fuel consumer than ever before. There are two reasons, first, fuel costs two or three times as much as it did a few years ago, and second, it has often been very difficult to get at any price during the past few years. The first reason is one that will remain. Prices of fuel, no matter what kind, will undoubtedly stay high, and in all probability will go still higher. The second reason, however, should vanish entirely when once labor and transportation facilities are properly controlled.

There is plenty of fuel for all who need it. The fuel given us by nature ready for use, will last for generations, but even when all our mines are exhausted and our oil fields pumped dry, there will be enough fuel in one form or another. Mother Nature will at that time again come to our protection with that greatest of her laws, the conservation of matter and energy. Carbon and hydrocarbons are really conserved by her unseen hand, but it remains for man to turn the key which will unlock her great storeroom.

The high cost of fuel therefore provides the principal incentive to save it



A. The average boiler plant does like this.



B. The best plants are doing like this.

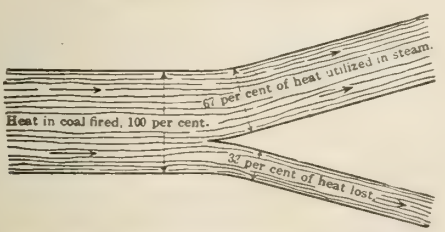


FIG. 1—DIAGRAMS SHOWING POSSIBLE IMPROVEMENT IN AVERAGE PLANT.

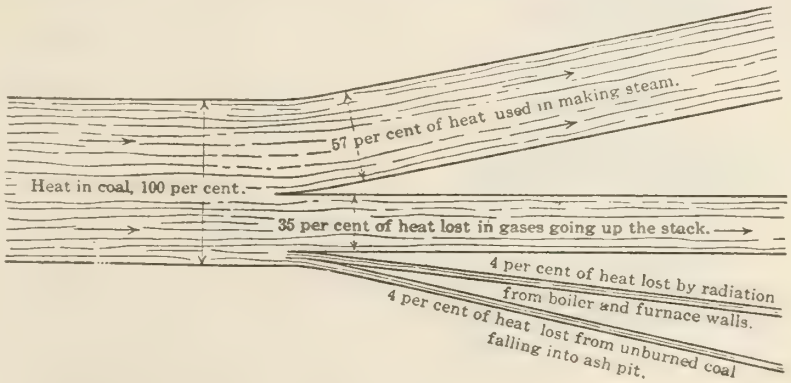
and the greater the cost the greater will be that incentive. The principal factors which enter into the cost of fuel are labor and transportation. Its price to the consumer will be governed by these two charges, plus whatever additional charge competition will permit the mining interests to add. As our resources are depleted, mining will become more difficult, and as production moves farther away from consumption, transportation charges are bound to increase. The price of fuel will, therefore, advance from year to year, until finally it will be cheaper to make artificial fuel, such as alcohol. In all probability, however, the cheapest fuel for our principal needs will be that which can be gotten out of the ground, as long as it lasts, in its ready-to-use form. That is why it should be made to last as long as possible through the practice of economy. However, since the price of fuel in the future does not seem to interest the present generation, the elimination of unnecessary waste should perhaps even be enforced by law for the benefit of posterity.

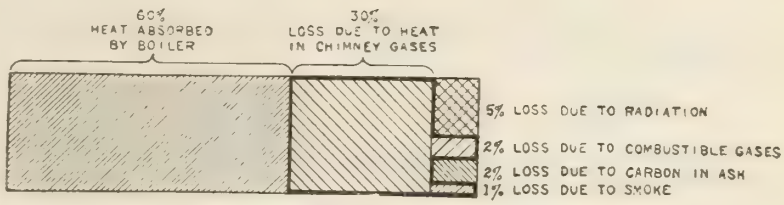
Over One-Third of the Fuel is Lost Up the Chimney

No matter how the fuel we use is consumed and no matter what kind of fuel is burned, whether solid, powdered, liquid or gaseous, the biggest loss is always due to the heat energy wasted up the chimney. In this connection it might be well to quote the following very conservative statement from Technical Paper No. 205, issued by the Bureau of Mines:

"In the average boiler plant, 35 per cent. of the heat in the coal burned under the boilers is lost with the stack gases. That is, out of every 100 tons of coal burned under the boilers, the heat of 35 tons literally goes up the stack. It is this loss that can be greatly reduced and every effort should be made to do so."



57 per cent of heat used in making steam.
Heat in coal, 100 per cent.
35 per cent of heat lost in gases going up the stack.
4 per cent of heat lost by radiation from boiler and furnace walls.
4 per cent of heat lost from unburned coal falling into ash pit.



60% HEAT ABSORBED BY BOILER
30% LOSS DUE TO HEAT IN CHIMNEY GASES
5% LOSS DUE TO RADIATION
2% LOSS DUE TO COMBUSTIBLE GASES
2% LOSS DUE TO CARBON IN ASH
1% LOSS DUE TO SMOKE

FIG. 2—WHERE THE HEAT GOES IN AVERAGE PLANT.
FIG. 3—CHART SHOWING HEAT DISTRIBUTION FROM COAL.

Figures 1 and 2, which are reproduced from the same Government bulletin, illustrate graphically the magnitude of fuel waste in steam boiler practice and show that the most important part of it is due to the loss up the chimney. According to the speaker's experience, however, this loss in the average plant is not less than 40 per cent., and in very many cases approaches 50 per cent. of the total heat energy in the fuel used.

The loss up the chimney, which is always the largest individual loss in any plant, depends for its magnitude on three factors. They are, in order of importance, first, excess air in the products of combustion; second, temperature of the products of combustion; third, amount of unconsumed fuel in the products of combustion.

Greatest Loss Due to Using Too Much Air

The excess air in the products of combustion results in a loss greater than

that from any other source. Each kind of fuel requires a definite amount of air to burn it, the exact quantity depending principally upon the ratio of its carbon and hydrogen. When considering coal, for example, the principal constituent is carbon, every pound of which requires 12 pounds of air to completely consume or oxidize it. All air that is used above this amount is with one square foot cross sectional area, it would have to be long enough to extend nearly from New York to Baltimore. Stated in another way, if the floor of a room were covered with coal to a depth of one foot, the ceiling would have to be over three miles high in order for the room to contain as much air as is generally used to burn that quantity of fuel. The fact that so much contains the major portion of the heat that is unnecessarily wasted. The exact amount of heat wasted in this way can be determined by the weight of the products of combustion per pound of fuel burned, and the temperature at which they leave the furnace or enter the stack. Thus, in the average plant, from one-third to one-half of the heat contained in the fuel is stolen by the

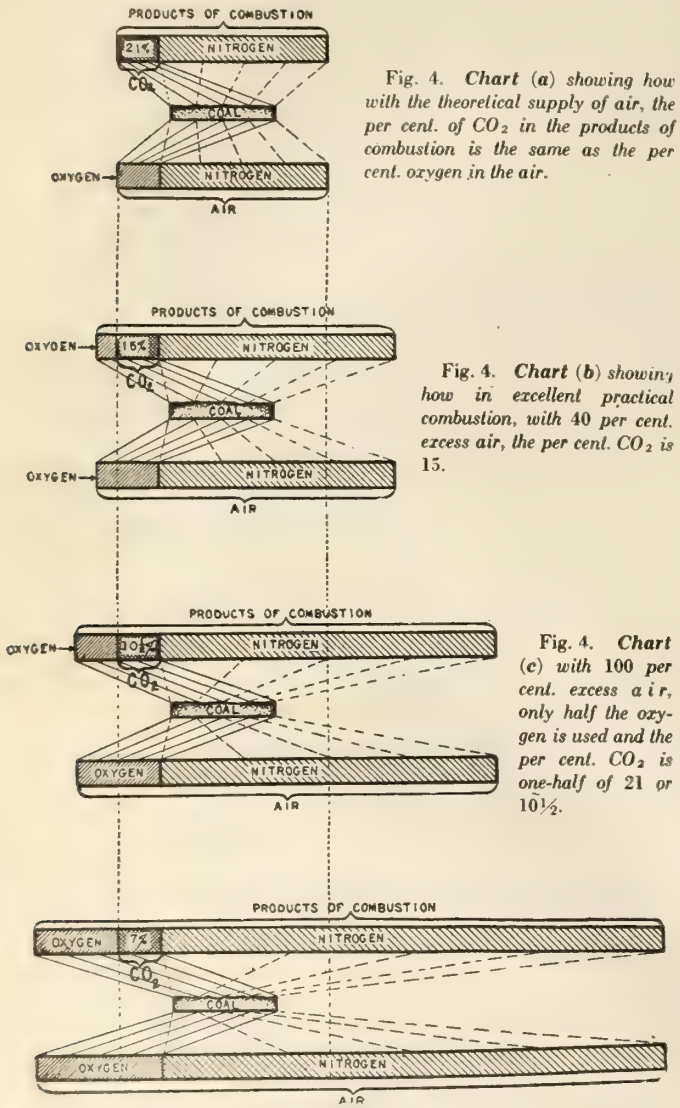


Fig. 4. *Chart (a) showing how with the theoretical supply of air, the per cent. of CO_2 in the products of combustion is the same as the per cent. oxygen in the air.*

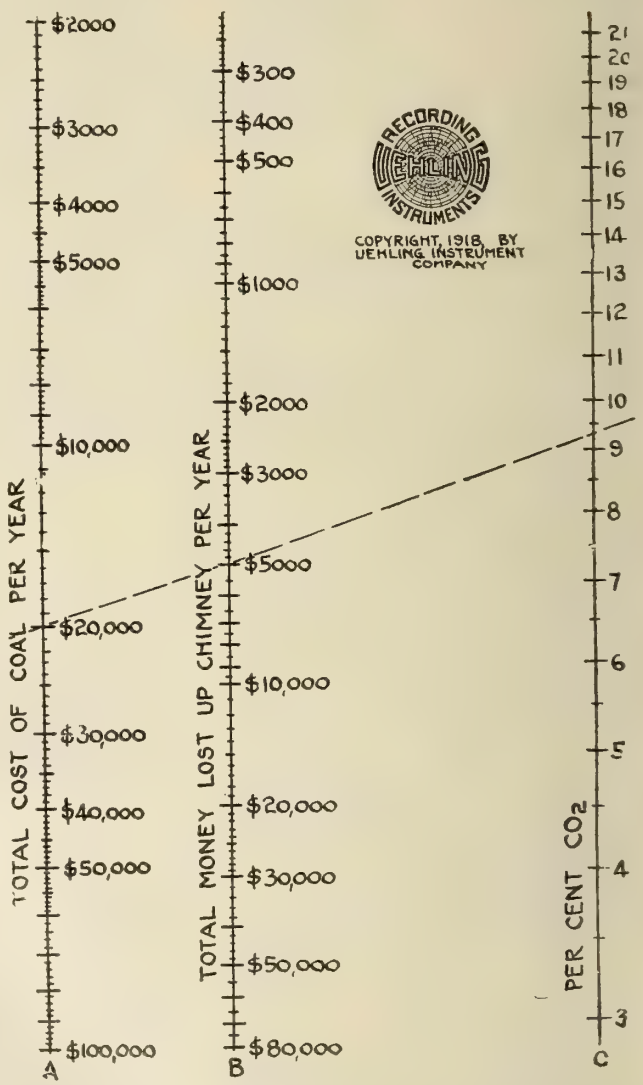
Fig. 4. *Chart (b) showing how in excellent practical combustion, with 40 per cent. excess air, the per cent. CO_2 is* 15.

Fig. 4. *Chart (c) with 100 per cent. excess air, only half the oxygen is used and the per cent. CO_2 is one-half of 21 or* 10½.

FIG. 4—SHOWING EFFECT OF EXCESS AIR.



SCALE SHOWING $ AND CO(2).

known as excess air, and when supplied in greater quantities than is necessary to meet the particular conditions of the furnace in which the fuel is burned, an unnecessary burden is immediately placed on the temperature possibilities of the furnace and the amount of fuel consumed to accomplish a desired result increases in proportion.

Even in fairly good practice, about 25 tons of air is used to burn one ton of coal, and in the more poorly operated plants this amount is often doubled. Twenty-five tons represents a lot of air. Under normal conditions it occupies a space nearly 16,000 times as large as the coal which it consumes. If the amount of air generaly used to burn one ton of coal were contained in a pipe air is consumed in burning coal is not realized by the fireman and the important relation which this huge mass bears to fuel economy is generally not given sufficient thought by his superiors. Although air costs nothing, and is available in unlimited quantities, when used to burn fuel in excess of what is required, as is the case in the average plant, it becomes one of the most expensive raw materials.

All the air that is used in burning fuel, whether under steam boilers or for any other process, appears in the products of combustion. If three times as much air is used as is necessary there will be just about three times as much products of combustion as necessary. This gas as it passes up the chimney products of combustion and dissipated into the atmosphere.

Smoke Not Necessarily a Sign of Waste

The other loss up the chimney, namely that due to unconsumed fuel in the products of combustion, is usually not so serious. The old idea that a smoky stack is a sign of tremendous waste is not always true, in fact, whether the gases leaving a chimney are smoky or smokeless is no indication at all as to the efficiency with which the fuel is consumed. Steam boilers, for example, connected with a stack that does not show the slightest trace of smoke may burn twice as much coal per pound of steam generated as when smoke is in great prominence. Black smoke is, of

course, unburned carbon, but the amount of carbon in this light and finely divided form that is necessary to give the products of combustion a dark or even a black appearance is generally only a small fraction of one per cent. of the actual fuel burned. The additional unconsumed fuel that is apt to be present in the products of combustion is carbon monoxide and hydrocarbons, both of which are caused by an insufficient air supply or the improper mixture of the air with the fuel before it is ignited. Although it is possible for the loss due to this cause to be serious, it is a fact that the average loss from this source can safely be estimated at less than two per cent. Figure 3, based on a representative test, gives a good idea of what becomes of the total heat in the coal and particularly how large a proportion of it is dissipated as sensible heat in the products of combustion.

Instruments Detect Chimney Losses

It is not the object of this paper to discuss any particular method of burning fuel. To minimize chimney losses, no matter what means are used, we must know whether or not the proper amount of air is being supplied, whether or not air is mixed with the fuel before it is ignited, and whether or not too much heat is left in the products of combustion as they pass up the chimney. Under all conditions these important facts can be determined by consistent flue gas analyses and temperature measurements. In so far as stack losses are concerned, the effect of any change in fuel or method of firing, the results of any additions or changes, or the value of any new appliance, can in this way be determined at once, and the best efficiency under the working conditions of any plant can generally be obtained and maintained without the necessity of lengthy and elaborate tests.

In 99 cases out of a 100, excessive loss of heat up the chimney is simply due to lack of facilities for determining whether the proper amount of air is supplied. When carbon, the principal constituent of any fuel, is completely burned, the result is carbon dioxide (CO_2). Complete combustion occurs when air is supplied in excess of what is needed. When, however, the air supply is reduced too much so that it is little more than that which is theoretically required, there is also a possibility of incomplete combustion due to an insufficient amount of air reaching part of the combustible. When this is the case some of the carbon in the fuel will become only half oxidized, that is, it will burn to carbon monoxide (CO) instead of to CO_2.

Heat Carried Away by the Dry Chimney Gases Per Pound of Combustible

POUNDS OF AIR PER POUND OF COMBUSTIBLE AND CORRESPONDING PERCENTS CO_2	TEMPERATURE OF CHIMNEY GASES, DEG. FAHR.

FIG. 5

Carbon Dioxide in Flue Gases the Key to Wasteful Air Supply

It must be remembered, however, that the big loss in practice is due to excess air and not to an insufficient supply. In order to clearly illustrate the importance of this fact, let us consider carbon as the fuel we are burning. Since carbon is the principal constituent of all fuels, the same reasoning will also apply to any other fuel, the principal difference being that the maximum obtainable percentage of CO_2 is less when fuels higher in hydrogen are used, due to the fact that hydrogen consumes oxygen to form water vapor (H_2O) instead of CO_2. Thus if one pound of carbon were consumed with the exact amount of air required to completely burn it, the 21 per cent. of oxygen in the air used would combine with it and appear as 21 per cent. CO_2 in the products of combustion for the reason that oxygen combines with carbon to form an equal volume of CO_2. On the other hand, if the same weight of carbon were consumed with twice the amount of air theoretically required to burn it, only one-half of the 21 per cent. of oxygen in the air used would combine with the carbon, the volume of the products of combustion would be twice as much, and the CO_2 content only 10½ per cent. Again, if the same weight of carbon were consumed with three times the theoretically required air, only one-third of the 21 per cent. of oxygen in that air would combine with the carbon, the volume of the products of combustion would then be three times as great as theoretically necessary and the CO_2 content only seven per cent. It therefore follows that the lower the percentage of CO_2 in the products of combustion the greater will be the volume of weight of the flue gases per pound of fuel burned, and the greater the temperature of this gas as it leaves its zone of usefulness the greater will be the loss per unit of its weight. This is clearly illustrated by Figure 4. In average steam boiler practice, for example, every pound of flue gas as it passes up the chimney is laden with sensible heat energy to the extent of from 100 to 200 heat units, and since there are from 25 to 30 or more tons of flue gas for every ton of fuel consumed, the magnitude of this tremendous loss can be readily appreciated. What it amounts to in actual heat units or in percentage of fuel used depends upon the percentage of CO_2 and the stack temperature. A table based on carbon as the fuel burned is shown in Figure 5. Such a table can be prepared for any kind of fuel. With fuels such as oil, which are high in hydrocarbons, the maximum percentage of CO_2 obtainable would be less, but every one per cent. drop in CO_2 would mean a greater increase in fuel wasted than a corresponding drop in CO_2 where a fuel richer

in carbon is used. The percentage of CO_2 in the products of combustion is therefore an index to the amount of air used per pound of fuel burned, no matter what commercial fuel is utilized. Several illustrations of this fact are shown in Figure 6. Chimney losses can thus be controlled, at least to the extent which the particular design of furnace will permit, by the simple regulation of the air supplied, so that the weight of the products of combustion per pound of fuel burned will be reduced to a minimum. The two most important constituents of the products of combustion, for determination by flue gas analyses, are, therefore, the percentage of CO_2 and the percentage of CO. The former should be made continuously by means of a CO_2 recorder, while the latter determination is only necessary when the percentage of CO_2 is so high that an insufficient supply of air to all or part of the fuel is suspected.

Chimney losses, as previously stated, depend upon three factors, the amount of excess air in the products of combustion, which is determined by the percentage of CO_2; the amount of unburned fuel in the products of combustion, the magnitude of which is indicated by the percentage of CO; and the temperature of the products of combustion, which can be determined with an ordinary flue gas thermometer inserted in the last pass of the boiler furnace, just before the gas enters the stack.

Of these three determinations the percentage of CO_2 is by far the most important. The percentage of CO_2 is something the fireman can easily regulate. If the brick setting of a furnace or of a boiler is made tight to prevent air in filtration it is an easy matter for him to decrease the excess air supply to 50 per cent. or less by simple cut and dry methods in the regulation of draft, thickness of firebed, etc., even though the excess air supply may have been 200 or 300 per cent. before he attempted to so regulate combustion.

The determination of the percentage of CO, being generally of much less importance, need be made only when there is reason to believe that incomplete combustion exists. In fact the majority of plants where CO_2 recorders are used, get remarkably good results, in so far as economy is concerned, without making CO determinations at all. In other plants, a series of tests are run for determining the maximum safe percentage of CO_2 without the formation of CO and the firemen are instructed to keep the CO_2 as near this point as possible without exceeding it. In many plants, however, the practice of merely instructing the firemen to keep the percentage of CO_2 as high as they can has led to surprisingly good results.

The third variable, namely the temperature of the products of combustion as they enter the stack, is one over which the firemen have no control at all.

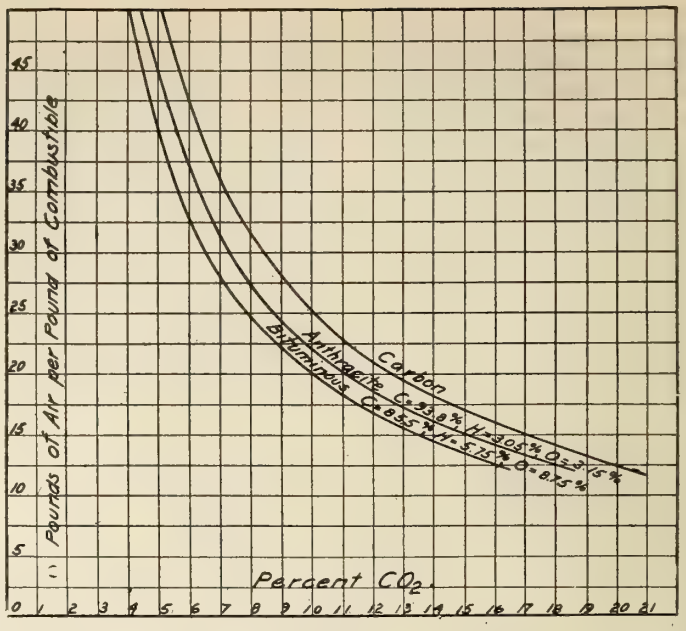

FIG. 6—CHART SHOWING RELATION OF CO_2 AND POUNDS OF AIR PER POUND OF COAL.

This temperature should, of course, be kept as low as possible, but it depends entirely upon how much of the heat in the furnace is absorbed or utilized before the products of combustion make their final exit. In boiler practice, for example, stack temperature depends upon the area of the heating surface over which the hot gases pass and the cleanliness of the heating surfaces. The lower the stack temperature, the less will be the heat wasted; on the other hand the higher the percentage of CO_2 the less will be the volume of flue gas to carry away valuable heat energy as it passes up the chimney. Since the temperature of the products of combustion does not vary materially during short intervals of time, the percentage of CO_2 by itself becomes a most reliable index to the greatest loss of all — the sensible heat energy wasted up the chimney.

Savings by Controlling Chimney Losses in a Small Plant

As a typical example of what can be done to save fuel by the simple regulations of the percentage of CO_2 it will undoubtedly prove of interest to compare the two CO_2 records as shown in Figure 7. They were made at a small New England plant. A CO_2 recorder was connected with the boilers and placed in the office of the chief engineer without the knowledge of the firemen. They knew, however, that a 24 hour evaporation test was to be conducted and were instructed to utilize every effort to maintain the load during that period with the least possible amount of fuel. Although they worked hard to make a showing for themselves the chart on the left illustrates that great variations occurred in the percentage of CO_2 and that the average was quite low. After the test had been completed, an auxiliary CO_2 indicator was placed at the boiler front for the firemen's particular benefit. They were advised that another test of the same duration would be run, but that this time only two things would be expected of them, viz., they were to maintain the steam at the required pressure and keep the CO_2 as high as possible. Not having heard of CO_2 before, the chief engineer simply pointed out the indicating column with

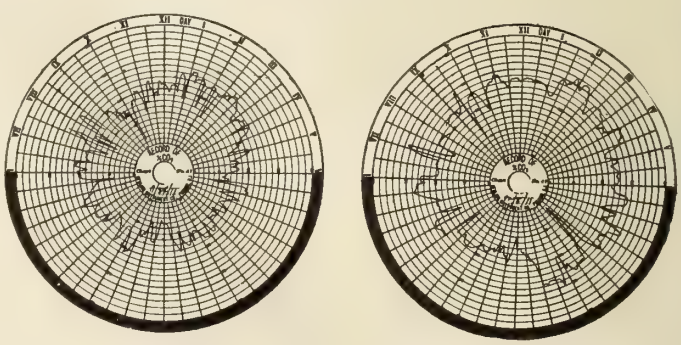

FIG. 7—COMPARATIVE CO_2 CHARTS AFTER INSTALLATION OF INSTRUMENT. THE CHART AT RIGHT WAS TAKEN SEVERAL WEEKS LATER THAN THE LEFT.

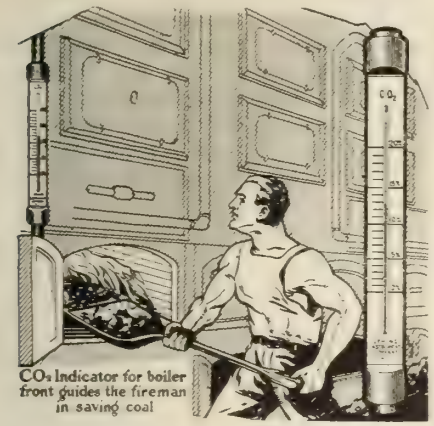
a statement that it must be kept high and that the way to keep it high was to make the necessary adjustments of draft, thickness of firebed, etc. They were particularly instructed, however, to make only one change at a time in any adjustment, and then note the result; if the indicator went up they would know that the change was made in the right direction and if it went down they would know the change was made in the wrong direction. They were allowed to use their own ingenuity and to



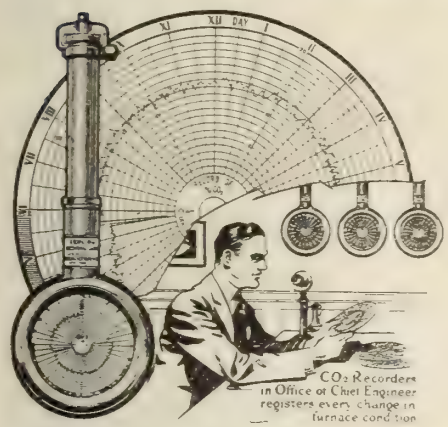


FIG. 8 AND 9—INSTRUMENTS FOR RECORDING AND INDICATING CO_2.

manipulate all furnace adjustments as they saw fit. They soon gained confidence and in a few days expressed their belief that the proper ratio of air to fuel burned could be maintained by watching the CO_2 indicator and making adjustments accordingly. The second evaporative test was thereupon started. The chart on the right hand side shows the results. This record is consistently higher than the first and the percentage of CO_2 is comparatively free from irregularities. The actual test showed a saving of 9.9 per cent. made solely by the efforts of the firemen who had never heard of CO_2 before. Showings of this kind are being made repeatedly at hundreds of prominent and smaller plants throughout the country.

Figure 8 shows the instruments used for determining the percentage of CO_2. The one on the left serves as a constant working guide for the firemen, while the one on the right simultaneously traces a record of CO_2 on a chart in the engineer's office, thus enabling him to keep tab on the work of the fireman.

The scale, Figure 9, will be found useful for estimating the value of the fuel lost up the chimney due to low CO_2. It is based on 600 degrees chimney temperature and high carbon fuel.

Toronto No. 2 Lodge Has Festive Evening

A HIGHLY successful and enjoyable meeting, followed by an informal supper was held by the Toronto No. 1 Lodge on Wednesday, October 27th. The guests of the evening were the members of the Hamilton Lodge, a number of whom motored over from the "city by the hill" to attend the event. The Hamiltonians present were Brothers A. Heath, A. Leckie, W. Tabor, W. Webb, W. Daly and L. J. Ellis, the latter gentleman being the Grand Secretary of the organization.

The Hamilton deputation were somewhat late in arriving, being delayed by reason of the highway being under repair. Indeed, from what some of them said later, it appears that the journey had been fraught with many perils, and there had been times when they had expected the two gallant "Lizzie's" that carried them, to founder with all hands. However, it would take more than bad roads and stormy weather to deter an engineer, so the party arrived in safety.

The chair was taken by "Dad" Wickens, the Hamilton guests being arranged to the right and left of the chairman. Other invited guests present were Messrs. Gordon Keith, of "Canadian Manufacturer," Grant Cole, Chas. Mosely, of the examining board, Howard Fletcher, and T. H. Fenner, editor of "Power House."

After an excellent supper had been disposed of and cigars passed round, the toast of the King was loyally honored, and following this, "Dad" Wickens spoke briefly on the subject he knows so well, the C.A.S.E. He passed briefly over its early development and the varying success that had attended their efforts, and then of the brighter prospects that opened before the organization to-day under the Dominion Charter.

L. J. Ellis, Grand Secretary, speaking in reply to the toast of the Grand Lodge, spoke of the efforts that were being made by the Grand Lodge officers to weld the organization into a cohesive whole. He exhorted the members to pull together and do each one his little best to help the other. Mr. Ellis spoke appreciatively of the opportunity given the lodges by "Power House" to publish their meetings and any events of interest. This, he said, would materially assist the work of the Grand Lodge in keeping the different lodges in touch with each other.

Mr. R. C. Leach, Grand President, spoke along the same lines, and said that by next convention there would be a bigger and better organization. They expected shortly to have affiliation with the North-Western Electrical and Mechanical Engineers of Edmonton, which was practically an offshoot of the C.A.S.E.

Mr. Keith, speaking as the secretary of the Exhibitors' Association, promised the members a good exhibition at the next convention. He also took the opportunity of adding a word of commendation for "Power House," of which he was editor at its inception.

The members of the Hamilton Lodge all spoke briefly in testimony of the pleasure it gave them to be at the meeting. They too breathed the spirit of progress and loyalty to the C.A.S.E. and its members, and also voiced a spirit of friendly rivalry with their Toronto brethren.

Mr. Harding, secretary of the Toronto Lodge, proposed the toast of the "Technical Press," and Mr. Fenner was called upon to respond. In doing so, Mr. Fenner took the opportunity to thank the members for their appreciative comments on Power House, and assured them that its pages were always open for the expression of their views and for comparing their experiences. He hoped the lodges would avail themselves of the invitation extended to them, and thus gain some much needed publicity.

The meeting concluded with "God Save the King," and the Hamilton deputation embarked once more on their faithful "Lizzies" for the run home. At the time of writing this we have not heard of their arrival. On the other hand, not having heard to the contrary, we will trust that they are safe in the shelter of their beloved mountain.

BUSINESS PAPER EDITORS' MEETING

Clay C. Cooper, Mill Supplies, Chicago, was elected president of the National Conference of Business Paper Editors for the ensuing year at a meeting held in connection with the annual deliberations of the Associated Business Papers, Inc., at the Hotel Astor, New York City, Oct. 20 and 21. The other officers chosen were: Vice-president, C. J. Stark, The Iron Trade Review, Cleveland; secretary-treasurer, R. Dawson Hall, Coal Age, New York. The executive committee is composed of A. I. Findley, Iron Age, New York; C. T. Hawson, Railway Maintenance Engineer, Chicago; A. R. Kennedy, Canadian Machinery, Toronto; James H. Stone, Shoe Retailer, Boston; H. L. Parmalee, Metallurgical and Chemical Engineering, New York; and Arthur L. Rice, Power Plant Engineering, Chicago.

A Course of Instruction for the Graded Certificate

We Will in This Course Go Through the Mathematical and Theoretical Work to Cover Every Grade of Certificate Issued by the Ontario Board

By T. H. FENNER

WE have covered a good portion of the horizontal boiler and will go into the question of reinforcing openings for mountings, etc., to some extent. A few lines on practical problems dealing with setting, etc., and one or two points dealing with calculations on furnaces of internally-fired boilers, and we can leave this subject. The reader who has followed this course should have gained enough knowledge to enable him to apply any of the rules relating to boiler construction that he may come across, and be ready to take up some further branches of engineering study.

Other Types of Boilers

Although our calculations have been confined to the H. R. T. boiler, most of the problems connected with other types are covered by the same work.

In the water-tube boiler with cylindrical steam and water drums, the strength of the drum is calculated by the same method as the shell of the H. R. T. boiler. The drum of the water-tube boiler is of small diameter, and on this account it is usual to use a double riveted lap joint on the longitudinal seam. The ends of drums or heads on the B. & W. type of boiler are usually of the convex type. Another place where this type of head is used is on steam domes. The advantage of using this form of construction for a dome head or drum end is that it requires little staying if a portion of a sphere, or none at all if it is hemispherical in form. The working pressure allowed on a hemispherical end is double that allowed on a cylinder of same size and thickness.

It is not unusual to find steam domes on boilers with heads unstayed, and the radius to which the heads are bumped may easily be determined by a simple measurement and calculation. Measure across the dome at the point where the flange commences, or where the plate is bent round to form the flange. From this line, which can be formed by placing a straightedge across, measure the height to the centre of the dome. Then the radius can be found by the following:

$$2r = h + \frac{C^2}{4h}$$

$$r = \frac{h + \frac{C^2}{4h}}{2}$$

If in the illustration the dome is 24 inches diameter and the length of the cord C is 23 inches, and height h is 4 inches, then the radius of the head will be

$$r = 4 + \frac{\frac{23 \times 23}{4 \times 4}}{2}$$

$$= 18\tfrac{1}{2}$$

This means that the head may be considered as a portion of a sphere of 37 inches diameter. The British B.O.T. rule for a bumped head, which is a portion of a sphere, requires staying but allows 18,000 pounds per square inch on steel stays.

When a dome is fitted to a boiler it should be stayed to the shell, whether the head is strong enough or not. The staying relieves the shell of a very severe stress and the portion of the shell under the dome should not be cut away entirely. It should be merely cut out sufficiently to allow steam to fill the dome. The form of staying shown in the illustration, where the stays are secured to the side of the dome, is a very poor method. While staying the head it leaves all the stress on the rivets holding the dome to the shell. The direct stay is good, and the third form of dome requires no staying at all. That is as far as the dome itself is concerned, it is the strongest possible construction. Generally speaking, domes are gradually dying out, and the modern dry pipe practice is much to be preferred.

Reinforcing Openings

Wherever an opening is made in a boiler shell and is over 2 inches in diameter, the shell should be reinforced to make up for the metal lost. The sectional area of the reinforcing ring should be at least equal to the metal cut out, and in many cases is required to exceed that amount. Supposing we have to reinforce a manhole opening on a shell 16 by 12 inches.

The long axis of the opening is always placed at right angles to the axis of the boiler when the manhole is in the shell. The amount of metal cut out will be

$$\frac{\pi}{4} \text{ — } Dd$$

where D= long axis and d=short axis. This is the formula for the area of an ellipse, and substituting figures we will have

$.7854 \times 16 \times 12 = 150.8$ square inches.

Now to reinforce this opening we will have to place a ring round its edges wide enough for riveting with a double row of rivets and at least of equal area. We have to allow for two rows of rivets, and if the plate is ⅜ in., that will be ¾ in. rivets. The distance from the edge of rivet hole to edge of plate wil be at least ¾ inches, and adding the rivet hole will be 1½ inches. Allowing a diameter between rows of rivets gives 2¼ inches and for the second rivet hole and lap to edge of plate is another 1½ inches, which makes 3¾ inches. We would then have for our ring a long diameter of $16 + 3.75 \times 2 = 23.5$, and for the short diameter $12 + 3.75 \times 2 = 19.5$.

The area of this is

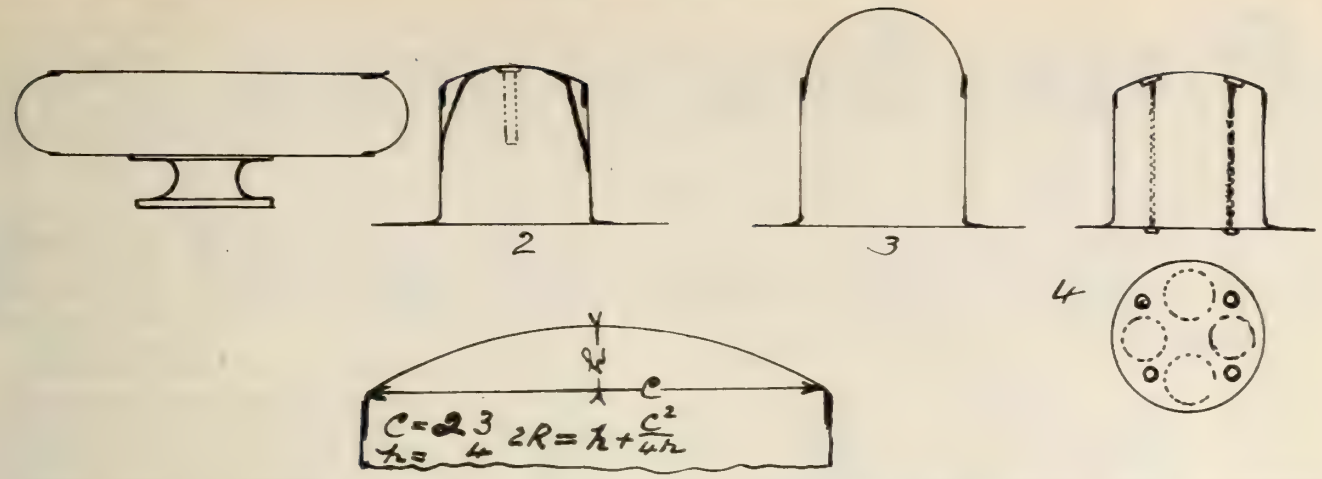
$$\frac{\pi}{4} \text{ — } 23.5 \times 19.5 = 360.$$

From this subtract the area of the hole 150.8 and we have 209.2 square inches, which is more than required. However, as the fault is on the right side it does not matter. It could be reduced by making the width 4 rivet diameters instead of 5, which would give 160 square inches.

It is usual to reinforce the opening in the bottom of the shell where the blow-off pipe is fitted, this usually being done by fitting a pad. In well-finished boilers, pads are fitted to the openings for water column fittings. The openings for steam pipes and safety valves are generally fitted with presesd steel nozzles riveted to the shell, which perform the function of attachment and reinforcement at the same time. This is usual in modern practice. Steam is collected in a perforated pipe inside the shell of the boiler, known as a dry pipe. Any moisture in suspension is usually separated form the steam in entering this pipe and falls back to the steam space. This dry pipe arrangement has practically superseded the dome.

Vertical Fire Box Boilers

The joint on the shell plates of a vertical boiler is calculated in exactly the same manner as the longitudinal joint in the horizontal boiler. It is of course exactly the same thing. The furnace is usually made of one plate, riveted either single or double lap. However, the stress on the furnace is a collapsing one as against the bursting stress on the shell. It is usual to consider the furnace of a vertical boiler as a flat plate, neglecting the strength due to its form. The strength then is considered as being due to the thickness of plate and the pitch of stays, and is covered by the formula



FIRST DOME THAT REQUIRES NO STAYING. 2. WRONG METHOD OF STAYING. 3. HEMISPHERICAL HEAD. 4. CORRECT METHOD OF STAYING. METHOD OF FINDING RADIUS OF HEAD.

$$\frac{C(T+1)^2}{S-6} = \text{W. P.}$$

where C=a constant varying with conditions from 120 to 200
T=thickness of plate in one-sixteenths.
S=Surface supported.

The surface supported will of course depend upon the pitch of the stays, and the stress allowed on stays. For screwed stays such as are used in firebox staying, the stress allowed is usually 8,000 pounds per square inch. The effective area of staybolts is of course taken at the bottom of the thread.

Plain and Corrugated Furnaces

The formulae for the collapsing pressure on plain and corrugated furnace tubes have been determined empirically and the candidate for examination will have no trouble in following them out. They are simple arithmetical problems. The strength of a plain tube varies according to its length and diameter, the longer and larger it is the weaker it is; of course the thickness has the effect of bringing up the strength, but a furnace wall must be kept as light as possible. With a corrugated furnace the length does not affect the strength, this thickness and diameter being the main considerations. The formulae are as follows:

$\frac{806300 \times t^2}{L \times d}$ = Collapsing pressure on a plain tube.

$\frac{90000 \times t^2}{(L+1) \times d}$ = Limiting working pressure on plain tube.

$\frac{14000 \times t}{d}$ = W. P. on corrugated tube.

where L=length in feet
t=thickness in inches
d=outside diameter in inches (measured at bottom of corrugations).

We think that enough has been said on the subject of strength of boilers for the purpose of these articles, and will take up new ground in our next articles.

The writer will gladly make clearer any points on which a reader requires further information.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

Question:—We have a return tubular boiler 60 inches diameter by 12 feet long. What height should the chimney be to obtain a draught of say .25 inches water?

Answer:—There are various rules for chimney height. The intensity of the draft of course depends on the height of the unbalanced column of hot gases, or in other words, the height of the chimney. The diameter will, of course, depend on the grate area, and in the case of a single boiler, the chimney area should be from 1-7 to 1-6 the grate area. It does not matter if the chimney area is a bit large, as it can always be reduced by dampering. There is always a portion of the chimney near the wall ineffective. A fairly simple rule given by Kempe is:

$$h = \left(\frac{W}{14a}\right)^2$$

Where h = height;
W = lbs. coal per hour;
a = area.

The coal burnt per hour with natural draught would be approximately 300 lbs. per hour on a boiler this size, and the area of chimney would be

$$\frac{25}{8} = 3.125 \text{ sq. ft.}$$

$$\text{Then } h = \left(\frac{300}{14 \times 3.125}\right)^2 = 47 \text{ feet.}$$

This formula does not give the draft which can be found from the following

$$d = h\left(\frac{7.6}{t \times 460} - \frac{7.9}{T \times 460}\right)$$

Where d = draft in inches of water.
h = height.
t = temperature of atmosphere say 60 degs.
T = temperature of gases say 600 degs.

$$\text{Then } d = 47\left(\frac{7.6}{60 \times 460} - \frac{7.9}{600 \times 460}\right)$$

d = .33 inches.

To find any specified draft reverse the formula. Say you want ¼-inch or .25 draft:

$$h = \frac{.25}{\left(\frac{7.6}{60 \times 460} - \frac{7.9}{600 \times 460}\right)} = 34 \text{ feet.}$$

Question. — Would it be asking too much of you to tell me briefly, "What are the advantages of a shaft governor

(Continnued on page 498.)

Another Harmless Boiler Explodes

ONCE again has a boiler, used on a farm for the purely agricultural purpose of threshing, proved that it is not exempt from the physical laws that govern other steam-containing, or pressure-containing vessels, though it is free from legislation. It proved this elemental fact by the very impressive means of blowing up, fortunately without hurting anybody. The men in the immediate vicinity had a very lucky escape, and those who were further away from the firing line were also fortunate, as some pieces weighing several hundred pounds were reported to have landed several fields away.

It shows surely a lack of consideration, or a sense of the fitness of things, on the part of these boilers to blow up when several successive governments have decided in their wisdom that these boilers cannot blow up, and are perfectly harmless domestic pets. The process of reasoning which decided that because a boiler is on a farm it is going to act differently under given circumstances than a boiler in an industrial establishment is not very clear to the ordinary mortal. Furthermore, the boiler on the farm is supposed to be possessed of sufficient intelligence to enable it to perform its functions without the aid of any skilled help. It is very likely that the real reason of the exemption of boilers on the farm from the Steam Boiler Act was on account of the farmers all possessing votes, and the fact that a farmer suddenly called upon to pay inspection fees, and probably higher wages to skilled help, would have emitted a howl that would have been heard uncomfortably in Queen's Park.

Our own opinion is that if there is any place on earth where a steam boiler should be subject to rigid inspection, it is on a farm, because anyone who has noticed the way many a farmer treats his farming implements can form a fair estimate of the way he will look after such a thing as a steam boiler.

We have pointed out from time to time in these columns the potentiality of danger that lies in any vessel containing a quantity of water under high steam pressure, and the fact that it was of relatively small size did not eliminate the danger. If one were to take the kitchen kettle and carefully seal the spout and tie the lid on after filling it with water, and then place it over the flame of the gas heater or the coal fire, it would probably blow the kitchen to pieces. The smallest boiler is much larger than the biggest kettle. Why should it be exempt?

The Cost of Strikes

THE Bureau of Labor Statistics at Washington has concluded that it is no use trying to compute reliable figures on the cost of strikes. All data pertaining to the matter, where an attempt has been made to reduce it to money, are of no value.

The bureau refers to the steel strike as showing the difficulties of gaining accurate information as to costs. Because of the difficulty of ascertaining the number of persons actually on strike and the different statements made by the two sides, it is held to be impossible to get figures of any value.

The innocent third party, the public, the bureau says, seldom suffers a money loss, its losses being mostly in the matter of inconvenience.

In Britain, right now, there is a concrete case of what it means to the third party. If the miners persist in their strike it will mean in a short time that hundreds of thousands of workers, who have no quarrel with their employers, and who cannot afford to do so, will be thrown out of work by reason of the absence of coal to keep their places of employment in operation.

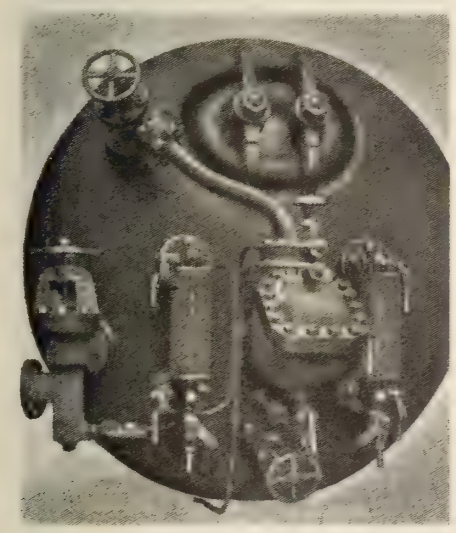
Progress in New Equipment

AN AUTOMATIC FEED REGULATOR

An automatic regulator for boiler feed water, made by A. G. Mumford, Ltd., of Colchester, in which only very simple mechanism is employed, is shown in the engravings and drawings on this page.

The regulator acts directly on the feed check valve and relies for its effect on the control of the leakage past a piston connected with the valve. The check valve is shown at A in the drawing, and it will be seen that the body is extended downwards to form a small cylinder, in which there works a piston attached to the check valve. The piston is quite an easy fit in the cylinder. A hand wheel and screw are provided so that the valve may be closed if necessary, but normally the valve is only controlled by the piston. At the bottom of the cylinder there is a drain pipe which is of such a capacity that it will carry away the water leaking past the piston through its clearance in the cylinder. As the areas of the piston and valve are equal and the feed water acts on both at the same time, the pressure of the feed cannot open the check valve against the boiler pressure until the pressures



ARRANGEMENT OF REGULATOR

on both sides of the piston are balanced. Such a balance can be effected by closing the drain-away from the bottom of the cylinder and allowing the leakage to accumulate beneath the piston. Thus, by regulating the drain the check valve can be controlled.

The valve E for regulating the drain is operated by a float in a chamber connected with the water space of the boiler. The plug cock on the drain at the check valve is merely for shutting off the regulator. The float chamber B

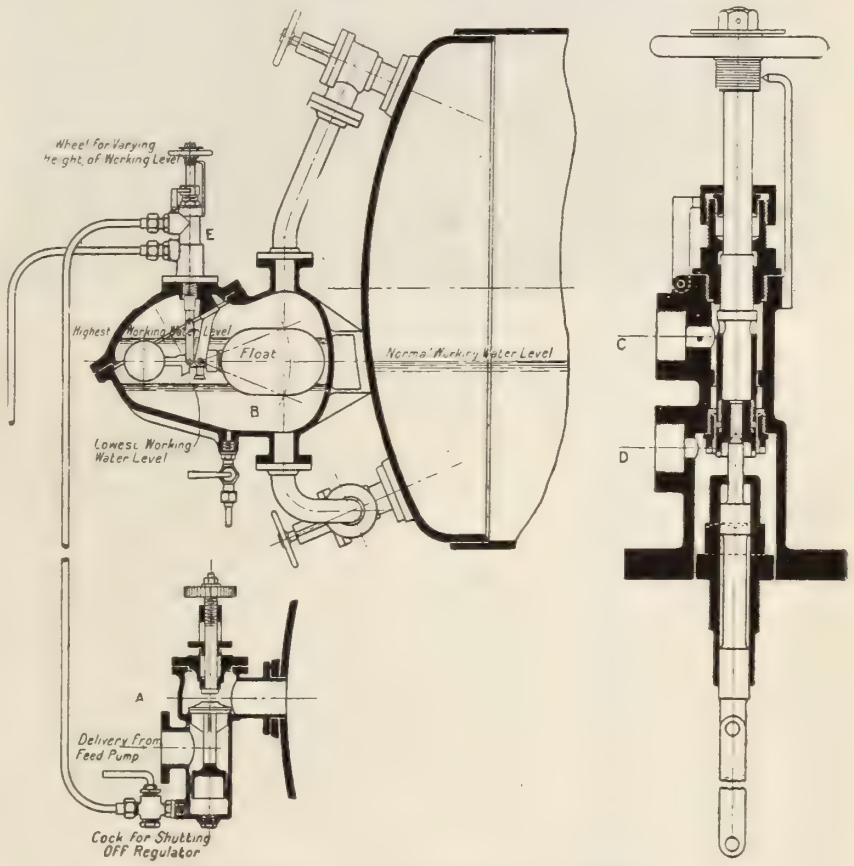


DIAGRAM OF FEED WATER REGULATOR.

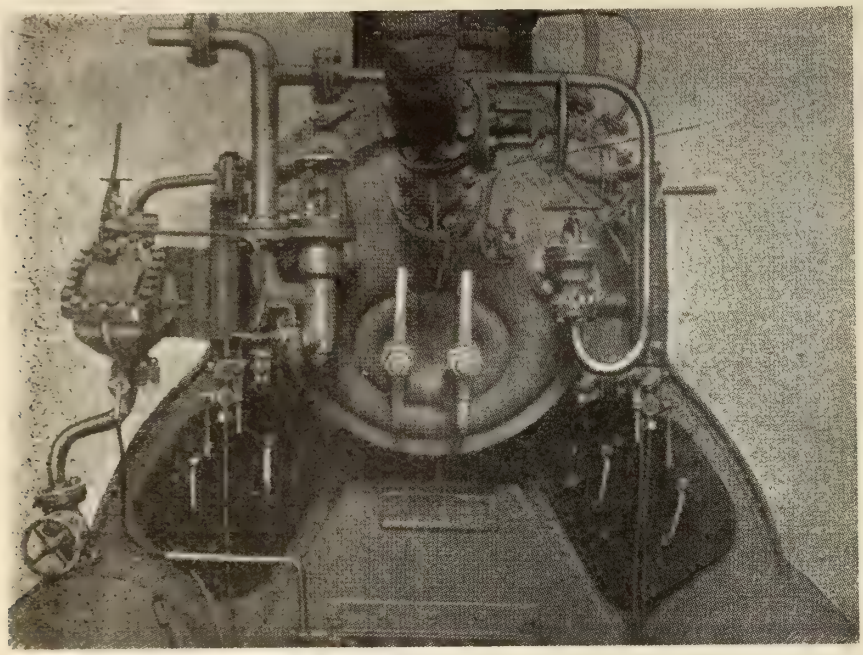
communicates with the boiler, both above and below the water line, and is so placed as to have its centre at about the normal working level. In it there is a substantial float, which is counterbalanced and pivoted on a bracket fixed to the chamber cover. A pair of links connects the float lever with the valve for controlling the leakage drain, of which a detail is given. The arrangement of the float lever and valve, it will be seen, is such that the valve closes when the float drops. Thus when the water level is lowered in the boiler the float closes the control valve, water accumulates under the piston and the check valve opens to admit water to the boiler. On the level in the boiler, rising above the normal the reverse action naturally takes place.

The leakage drain is connected with the valve at C, while a final drain leads from D to the feed pump suction. The seating of the control valve is fixed on the end of a long hollow spindle, which is screwed and furnished with a hand wheel at the top. It is thus possible to vary the position of the seating, and consequently the water level at which the float will close the valve.

It will be noticed that all the working parts of the mechanism are entirely within the casings, with the result that there are no stuffing boxes with their friction to check the free action of the gear. There is a spindle which comes through the wall of the float chamber in a stuffing-box; but it is quite separate from the rest of the mechanism, and is only used to test the freedom of the float. The spindle has a handle on the outside and terminates within the float chamber in an arm which can be engaged with the float lever. This arm

can be seen hanging just below the bracket carrying the float.

One of the great merits of the apparatus is the ease with which it can be overhauled while the boiler is under steam. If the valves in the pipes connecting the float chamber with the boiler and the plug cock on the check valve are closed, the whole mechanism can be opened up and hand regulation reverted to for the time, during which the automatic gear is out of commission.



ANOTHER ARRANGEMENT

FILTRATION AND STERILIZATION

To the man who is not vitally concerned the matter of machine tool lubrication may not appear of much importance. On the contrary, it is of proven importance, otherwise there would not be the demand for such a large number of different cutting oil liquids and compounds.

It was not so long ago when the ability to increase production by liquids applied to cutting tools was recognized and the initial steps taken along that line. Water was the first liquid tried, used as a stream feed, or provision made so it would be allowed to trickle upon the tool and work. A little experience in this way proved that a mixture of soda and water was more satisfactory all around, as the tendency to rust and corrode was largely overcome.

The evolution of machine shop practice, requiring high speed tools, carried with it efforts for extreme accuracy in machining and the element of increased production. With the speeding up of tools it was readily recognized that in order to keep down operating costs and produce a product of the highest quality, it would be necessary to use a cutting fluid which had not only the cooling properties necessary to absorb excess heat, but lubricating qualities as well, to increase accuracy, decrease the power consumed, and at the same time speed up production.

With the production of a cutting oil which would serve the double purpose came the increased cost and this item must, of necessity, be kept at the lowest possible figure, otherwise the product could not be marketed. It was, therefore, apparent that an equipment which would filter and sterilize the liquid would eliminate the necessity of throwing the used oil away. This method would reduce cutting oil expense and still promote high speed operation.

The S. F. Bowser Company, Limited, oil storage and filtration engineers, Toronto, are out to meet this need and have designed a filtering and sterilizing system which will soon be placed on the market. The illustration gives a good idea of its appearance and construction. These embody the tried and true principles of screening, precipitation, filtration and sterilization, all combined in a commercial and practical manner. This class of filtration is not a venture or experiment, and the company have had systems, essentially the same, in service for several years, which are giving the very best results.

An installation of this nature will naturally increase the life of the cutting tools, decrease power consumption, permit higher operating speed, increase accuracy, give better lubrication and save throwing away oil which has been used. By this conservation a better grade of oil can be used—one which will not foam, rust or corrode the work or tools. While the filtering process, which is automatic, is under way, the oil is also sterilized, thus eliminating obnoxious odors and preventing infection, thereby preserving the health of the employees.

The systems are so designed that they can be adapted to conditions prevailing and arranged to accomplish the work required. From the machines and chip separators the oil, either by gravity or special provision, can be delivered to the filter and sterilizer which automatically removes foreign matter and sterilizes the fluid. After going through a series of compartments, screens, filtering devices, etc., the liquid is delivered to the filter tank, which acts as a temporary storage. From this tank the oil can be returned to the different machines the same as new oil and used again.

POWER CAUSES MORE TROUBLE

Industrial Centres Have Hard Time in Keeping Their Plants in Operation

BRANTFORD.—The Hydro Commission here has been unofficially notified that a 20% reduction in Brantford's Hydro allotment will be made shortly. A conference of manufacturers and the local Hydro Commission will be arranged to take steps to prepare for the cut. The situation here is already serious and the city council committee in charge of street lighting is prepared to curtail this to provide more power for domestic users.

Windsor's Shortage

WINDSOR.—Deeming it necessary to bar use of Niagara power for signs and window lighting, the Windsor Hydro-Electric Commission will ask the city council to pass a by-law giving effect to a resolution passed at a meeting of the commission. O. M. Perry, manager of the local commission, said every effort will be made to discourage the use of electric heaters. Co-operation is necessary also on the part of business men, Manager Perry said, in order that street lighting may be provided in new residential sections.

OUR QUESTION BOX

(Continued from page 495.)

over a fly ball governor?" I have this question to answer at our next regular meeting night, October 26th. Not having much experience with a shaft governor, am kind of "up against it." After looking over some dozens of the Power House could not seem to find the point. As you have helped me out of difficulties before, I thought I would try you again.

Answer:—The advantage of a shaft governor lies in the fact that it acts directly on the steam distributing valve, and alters the cut off, thus getting a longer expansion curve, or in other words, more heat from the steam. The fly ball governor acting on the throttle valve curtails the opening through which the steam passes, causing loss of heat by wire drawing, and the cut off remaining the same, the steam leaves the engine at a higher terminal pressure.

FAIRBANKS-MORSE

Building a Bigger Canada

THESE are days of progress—days when industry is leaping ahead and Canada is assuming her place in the world of commerce. Giant structures are being reared to house the machinery, men and equipment necessary to a bigger business.

Great highways are being constructed to provide for the easier transportation of Canada's products; elevators, wharves, factories, mills, mines—everywhere the hand of the contractor is set to some big task.

And wherever this construction work is going on, Fairbanks-Morse contractors' equipment is playing an important part—rendering its services as a factor in this work of progress. From the shovel to the steam and electric hoists, from the concrete mixer to the heavy road machinery, drill and jack, to truck and railway car, Fairbanks-Morse equipment is the choice of the contractor, because he knows that behind the smallest tool is the same quality guarantee and service that supports the largest unit of Fairbanks-Morse equipment.

He knows that the Fairbanks-Morse 100% quality seal is the ideal of the Fairbanks-Morse institution—a standard and a guide in building a bigger Canada.

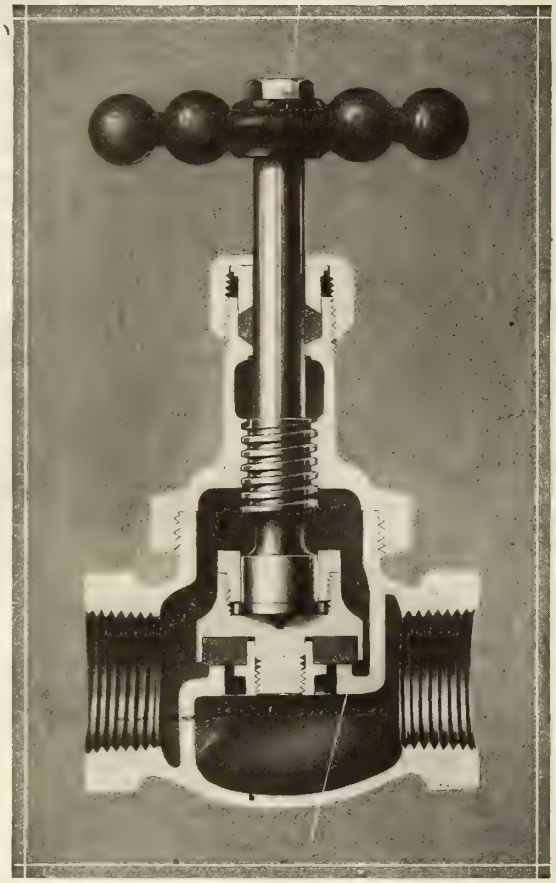
TRADE PENBERTHY MARK.

BE SURE THIS NAME is on the Valve you buy



SECTIONAL VIEW OF PENBERTHY COMPODISK VALVE
Registered and Approved for 175 lbs. Steam Pressure

Then you get "The valve with the outside bonnet construction."

The first progressive improvement made in brass valve construction in generations.

Think of the advantages! Valve always accessible.

No straining or stripping of threads when assembling or taking apart.

Impossible to spread or enlarge body of valve when screwing down bonnet to place.

No corrosion of threads, for they are on the outside, away from the action of steam and water.

Penberthy Valves Are High Grade Valves

The fine quality of metal—the excellent workmanship and finish—the up-to-date design with the outside Bonnet Construction—the long wearing, serviceable Composition Discs —the Government approval of 175 lbs. steam pressure—all these advantages are yours when you buy the genuine Penberthy Valves. We also make the Regrinding Type approved for 200 lbs. steam pressure, as well as Brass Gates, Swing, Horizontal, Vertical, and Angle Check Valves.

Tragedy in an Unusual Form

THE generation of high potential electric current and the transmission of it over many miles of country is attended by comparatively few accidents in proportion to the amount of electrical power development. The chief cause of fatalities through high voltage electric lines is by the coming into contact with them of linemen engaged in their usual work of running new lines, and repairing and locating faults in existing ones. Accidents in the generating stations themselves are happily few in number, and fatalities even less, and with the constantly better efforts towards safety that are being put forth, the number should steadily decrease. It is therefore with something of a sensation of horror that we read of the destruction of no less than eleven men, almost instantly, through an accident which, although it may have happened before, does not recur to our memory. The accident in question was the explosion by some fault in the insulation, presumably, of the oil used for the cooling of a transformer in the Tonowanda power house, Buffalo. The change of electric current, which is generated at high pressure, to current at a much lower pressure is accomplished by means of transformers which consist of two separate coils of wire wound on iron cores. The high potential coil will consist of a large number of turns of small wire, and the low potential side of a less number of turns of a larger wire. The effect of the high potential current being passed through the high potential coil is to induce a current in the low potential coil of the same periodicity, and the relation between them is such that if the high side A consists of 50 turns, and the voltage is, say 100 volts, then if the low side consists of 25 turns the voltage in that coil would be reduced to 50. This, of course, applies to any voltage, and any relation of the number of turns. There is little loss between the two sides, by which we mean that the product of volts and amperes in the low side will be almost the same as that of the volts and amperes in the high side. What loss there is, however, appears in the form of heat, and in order to carry off this heat, it is usual to immerse the whole apparatus in a bath of oil. This oil in turn has very often coils running through it which carry a circulating stream of cooling water, and thus the heat is effectually dissipated. It was this bath of oil that exploded and thrust forth a sheet of flame which licked out the lives of eleven men in an instant. The cause of the accident is stated to have been a short circuit. The apparatus was under test at the time, and it is probable that oil bath had been raised to a dangerously high temperature without it being noticed. A piece of defective insulation and a high tension spark would easily supply the little extra heat necessary to cause the flash. No doubt the enquiry that will follow will throw light on the exact cause of this sad accident, and make the recurrence of it extremely unlikely in the future.

TRADE GOSSIP

Equipment Wanted.—T. McAvity & Sons, Ltd., St. John, N.B., are in the market for a few No. 6 turret screw machines.

George A. Marshall, of Messrs. Marshall, Son & Bunney, 39 Richmond St. E., Toronto, has gone to England on the SS. Metagama, where he will spend a month or more on business matters.

At a recent meeting of the Montreal Branch of the Engineering Institute of Canada the entire evening was devoted to moving pictures, both of an instructive and entertaining character. One of the reels shown was in connection with the work of McGill University. Every branch of the work was covered by the film, including educational, athletic and military features. Between the showing of the pictures brief addresses were given by J. L. Busfield and the secretary F. S. Keith.

Locating in St. Thomas. — The Canadian Edison Phonographs, Ltd., have taken over the buildings in St. Thomas, formerly occupied by St. Thomas Cabinet, Ltd., and before that by Thomas Bros. The Edison Company took over the buildings, much of the equipment in the woodworking shops, and get six acres of land along with it. They have also placed orders for considerable new equipment in the line of woodworking machinery. The deal for the sale of the plant to the Edison Company was put through by Mr. William Garlock, of the Garlock-Walker Co., Toronto.

Will Finish Ships.—Arrangements are being made by the Department of Marine with the liquidator of the Dominion Shipbuilding Co., of Toronto, for the completion of the two steamships which that corporation had under construction for the Government of Canada. The vessels, which were being built for the fleet being operated by the Canadian Government Mercantile Marine, are to be of 3,500 tons each, and about 75 per cent. of the work upon them had been done when the company went into liquidation. The Department of Marine will either undertake to do the remainder of the work or have it done through the liquidator.

Following a conference held between the Administrative Commission and an influential delegation of business men and citizens of Montreal, headed by Lord Shaughnessy, a deputation will go to Ottawa to confer with the Government on the question of constructing a second bridge across the St. Lawrence in the vicinity of the harbor of Montreal, to connect the Island with the south shore. It is felt by a large number that this additional means of communication between the two points is an urgent necessity and that the next few years will demand some relief from the present conditions.

May Earn Less.—In commenting on the business prospects, President T. J. Dillon, of Canada Foundries & Forgings, Welland, Ont., says: "In order to realize on the full possibilities of the plants this company found on its hands at the end of the war, it was considered advisable to appropriate a fairly large amount for additional equipment for rounding out their different units to lower the cost of manufacture of regular lines and add a few new ones. Indications point strongly to gradually lowering on steel commodities, and lessened dividends, which will result in declining earnings. Although the common dividend declared was somewhat less than those previous, it makes 10 per cent. for the year 1920."

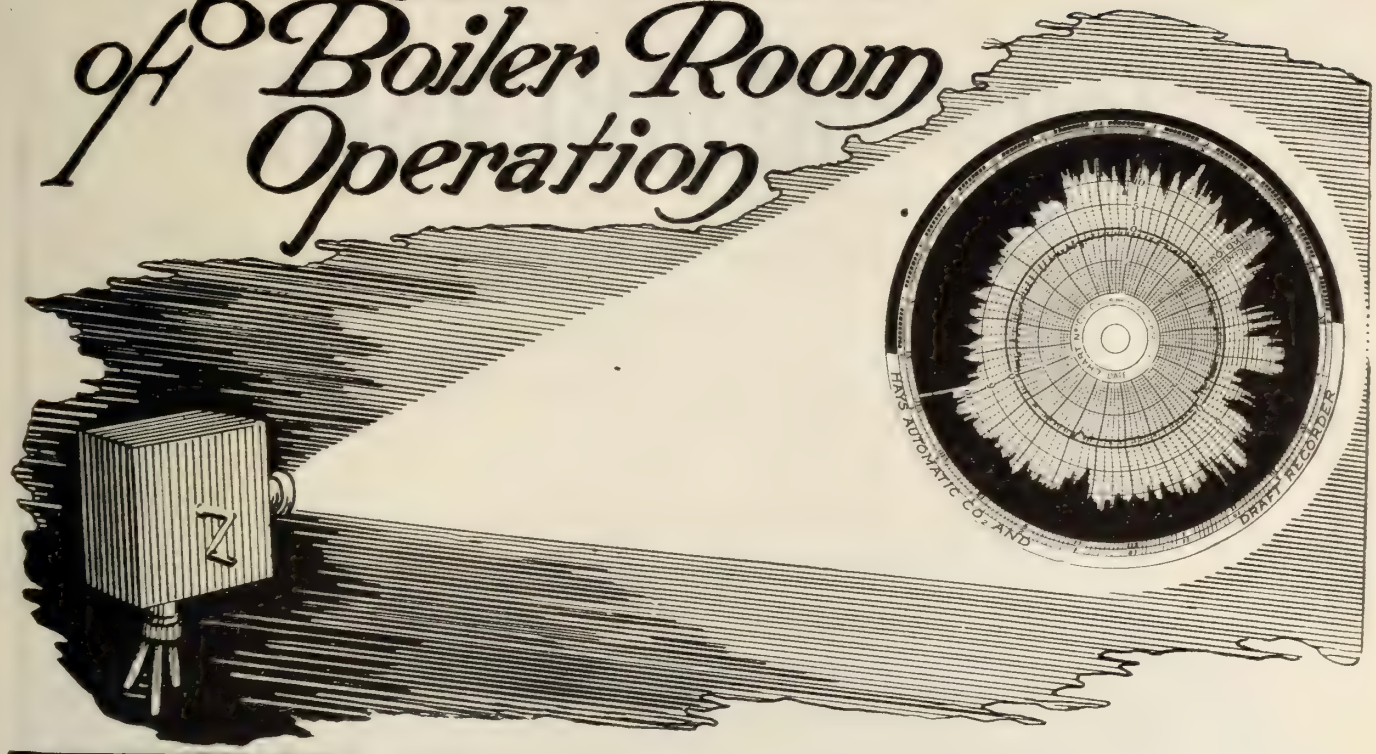
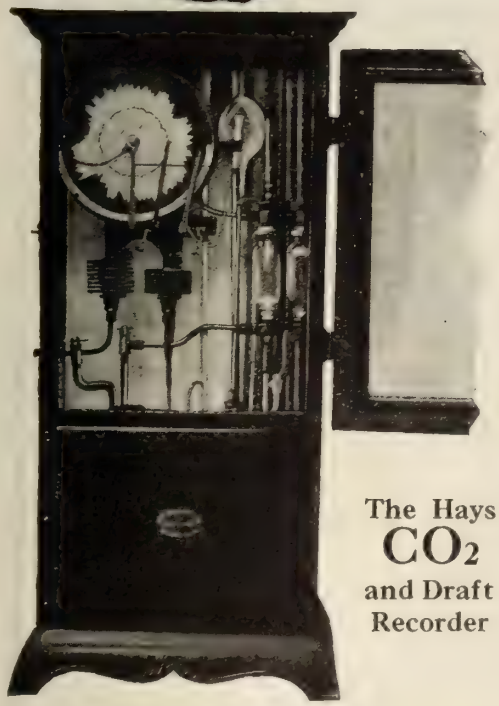
Moving Pictures of Boiler Room Operation





The Hays CO_2 and Draft Recorder

Awarded certificate of merit by Franklin Institute

The Industries have come to appreciate the value of pictures which show every important detail of an operation and enable careful analysis to be made. Waste motion is eliminated; higher efficiency and better products at a lower cost are the results when a scientific study is possible thru such a record.

The daily picture made by the **Hays Automatic Co_2 and Draft Recorder** shows cause and effect of Boiler Furnace Conditions. The fireman makes his own record. He sees trouble coming and takes measures to avoid it. He knows what to do and why to do it because he has analyzed by "reduced motion" the Hays Record of the performance of his equipment. He knows the draft and the fuel thickness which gives highest percentage of CO_2 under different loads, and firing to him means imposing these *best* conditions.

Department "S" will gladly send you complete data about Hays Appliances with a copy of the interesting Booklet "Fuel."

DURABLA
TRADE MARK REGISTERED

STRENGTH—GOODNESS—QUALITY

Performance Facts of Durabla Gasket Material

Tight joints are made and maintained by DURABLA under the following severe services and conditions:

Steam:	275-300 lbs. pressure; 275°-300° superheat.
Oil:	Pressure still joint re-made over 160 times.
Gasoline:	Cylinder heads of gasoline engines and pumps.
Acids:	All acids that can be carried in pipe lines.
Water:	Equally satisfactory with temperature of 40° or 210° F., at any pressure.
Ammonia:	Both absorption and compression systems of refrigeration.
Air:	Air lines and cylinder heads of compressors—all types.

One Standard material for all gasket work—Sold on a Service Basis

DURABLA is sold in sheet or gasket form and the trade mark is stamped all over the material.

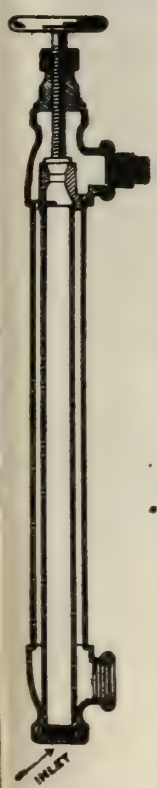
The LONG

PATENT

STEAM TRAP



Saves Coal

The Long (Patented) Steam Trap conserves fuel by stopping steam wastage.

Most simple and effective Steam Trap you can install in your plant. **Has only one Movable part.**

The Long Trap is open at the start and cannot become air bound. Never freezes. Works against 1 and 200 pounds pressure. Can be installed in any position.

Write us and we will send you the full story of its efficiency. 'Twill save you worry, time and money.

MALE HELP WANTED

MECHANICAL ENGINEER, PREFERABLY technical graduate, having steam-power-plant experience to assist in the preparation of technical-book manuscripts and in other steam engineering work largely of desk and detail character. Ability to write pure, simple, expressive English is essential. Teaching experience desirable. Must be accurate and thorough. We desire to locate a steady, well-balanced, painstaking engineer who does not ordinarily answer advertisements. To one who can satisfy our requirements we can offer a good future. Apply by letter only, in your own handwriting, giving age, education, experience (when and where you worked and what you did) and salary expected. Terrell Croft Engineering Company, 6600 Delmar Ave., University City, St. Louis, Mo. (p10h)

WANTED

WANTED AT ONCE — POSITION AS ENgineer. Hold second-class certificate. Steady, reliable man. Will go to any place. Box 101220, Power House. (f)

WANTED—EXPERIENCED BOILER DESIGNer by large manufacturing plant in Ontario. Apply Box 92120, Power House. (f)

GOOD INVENTIONS

ENCLOSED LIQUID FUEL COMBUSTION APparatus capable of generating intense heat in pipes and confined passages for heating parts of internal combustion engines and for other uses; spark ignited; blower operated. Patented October 8th, 1918. Can be inspected at and for sale by H. W. Petrie, Limited, 131 Front St. W., Toronto.

NON-CORROSIVE
CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
NOS. 242 & 244 SOUTH ST. NEW YORK, U.S.A.
FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done—give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

E. H. KELLOGG & CO.,
New York, U.S.A.

Do you realize the Grea Expense of Packing Stuffing Boxes to-day?

Everything is costly

The heaviest item of expense is the labor of applying the packing and not the packing itself.

It is therefore necessary that the heavy labor expense be minimized by using only the packing that gives the longest service.

Ask the Engineer who uses

TRADE MARK
"PALMETTO" PACKING
REG U S PAT OFFICE

and he will tell you how long it outlasts other packings.

If you don't know what "PALMETTO" packing will do for you in the way of saving needless trouble, and useless expense, ask us to send you working samples to test under your own conditions. It will cost you nothing for the samples and it will prove our claim.

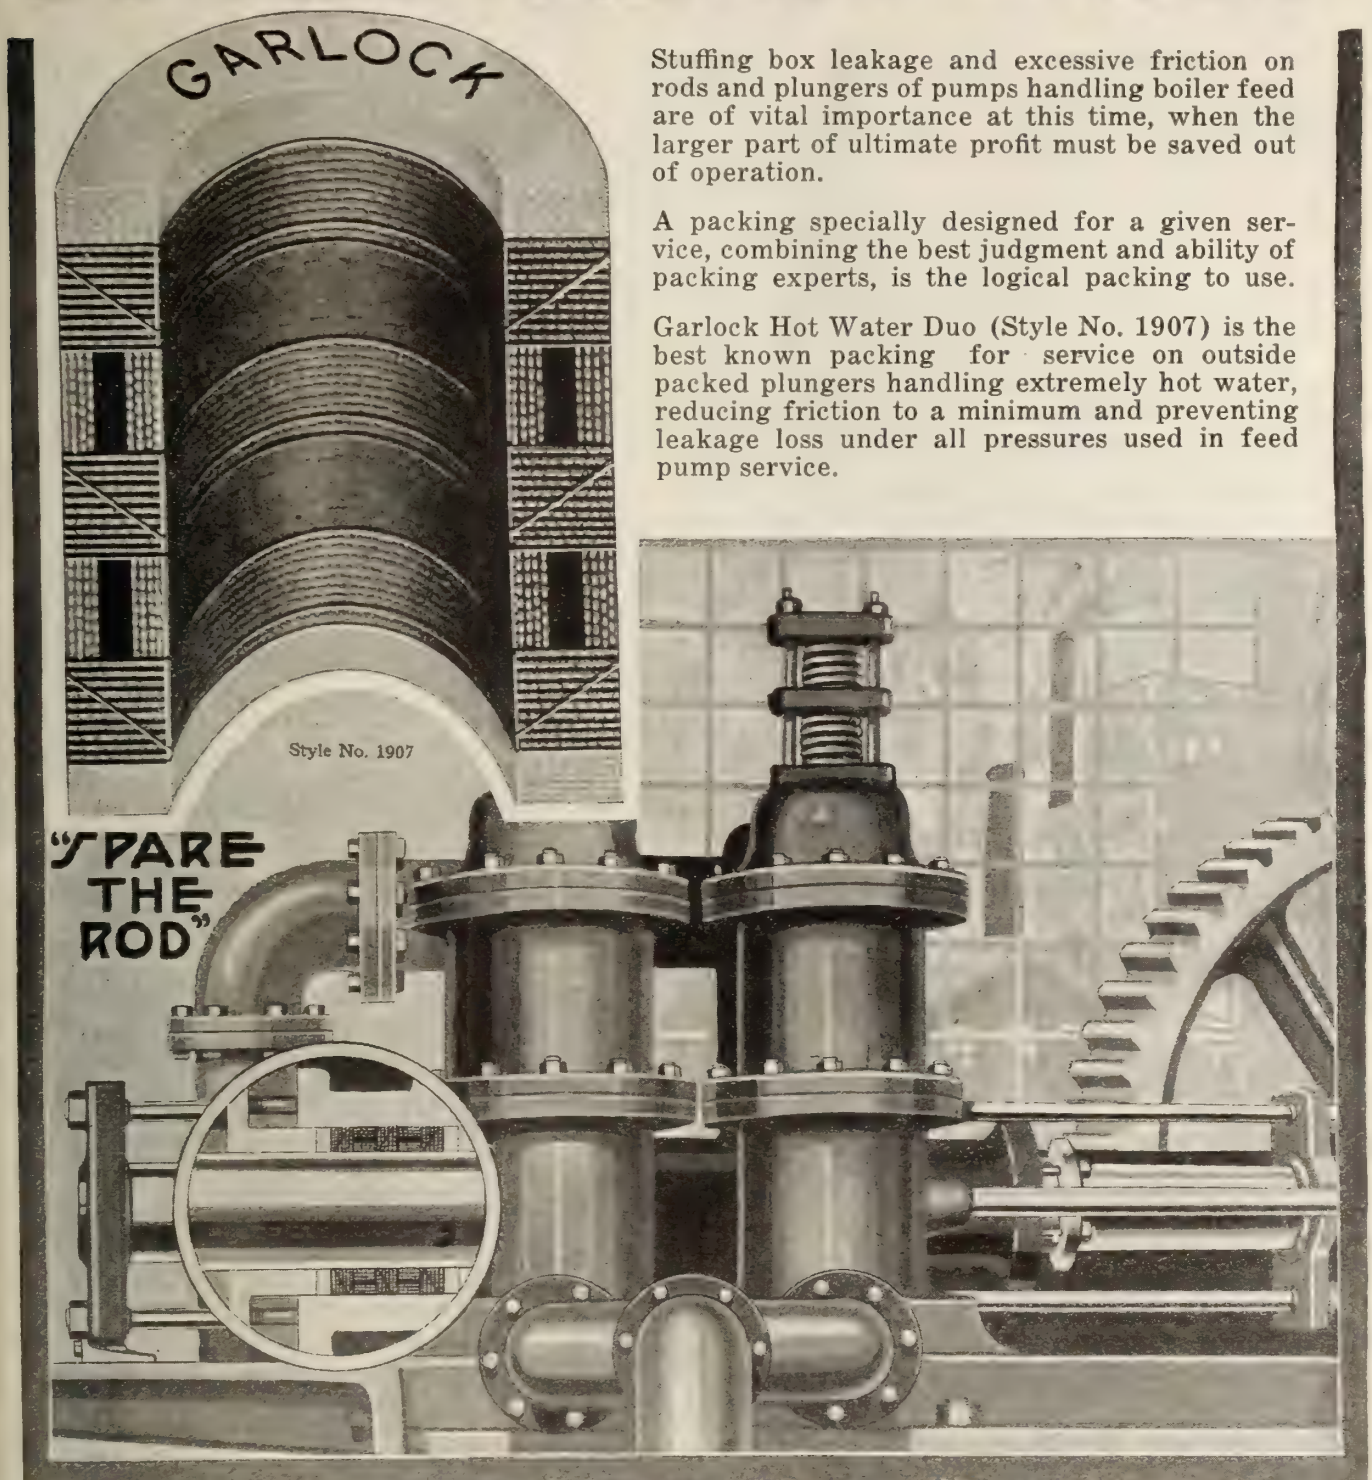
109 DUANE ST., NEW YORK

OUTSIDE PACKED PLUNGERS



Stuffing box leakage and excessive friction on rods and plungers of pumps handling boiler feed are of vital importance at this time, when the larger part of ultimate profit must be saved out of operation.

A packing specially designed for a given service, combining the best judgment and ability of packing experts, is the logical packing to use.

Garlock Hot Water Duo (Style No. 1907) is the best known packing for service on outside packed plungers handling extremely hot water, reducing friction to a minimum and preventing leakage loss under all pressures used in feed pump service.

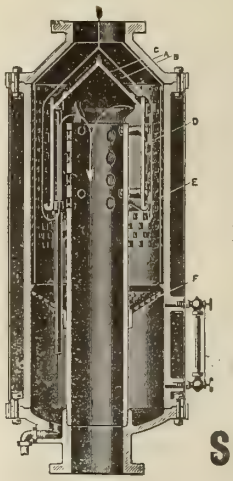
III IMPORTANT THINGS
TO CONSIDER ABOUT A SEPARATOR



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE — Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION — Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

Sweet's Separators

Coppus in the Confectionery Industry

Wherever candy is sold Huyler's trade-mark means quality supreme. Wherever candy is made—there is an opportunity for COPPUS Turbo Blowers to save money in power plant operation.

These two 18" Blowers have been economizing time, fuel, and labor in the boiler room of the Huyler's Chocolate Company, 136 East 18th Street, New York City, since July, 1917. They burn inexpensive fuel—keep up full steam pressure—and meet peak loads without extra exertion by the engineer, **quickly, easily, cheaply.**

They can do this better than any other type of blower because of their

Standardized Construction
Rugged Reliability
Economy of Operation

What COPPUS Turbo Blowers are doing in other plants they can do in yours. If you will ask us we will be glad to send you complete information showing just how COPPUS Turbo Blowers can help you secure more power from your present equipment and greatly increase the efficiency of your power plant.

Write for Blower Catalog.

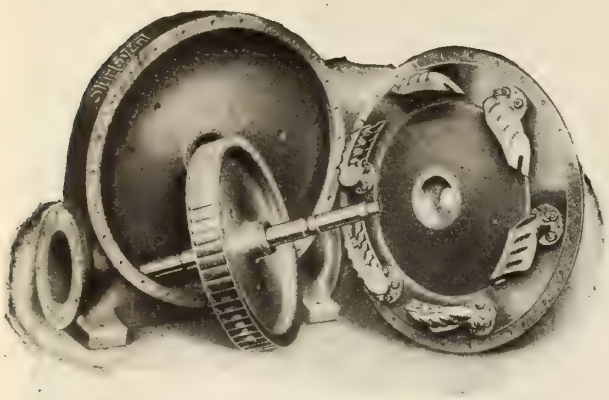
COPPUS TURBO BLOWER

For Low Cost



Contrary to popular belief, a careful comparison of the steam consumption of an engine and of a turbine of equal capacity will show that they run closely together when both are new.

At the end of a short period of operation the wear on the engine valves will have materially decreased the initial economy while that of the turbine remains practically unimpaired.

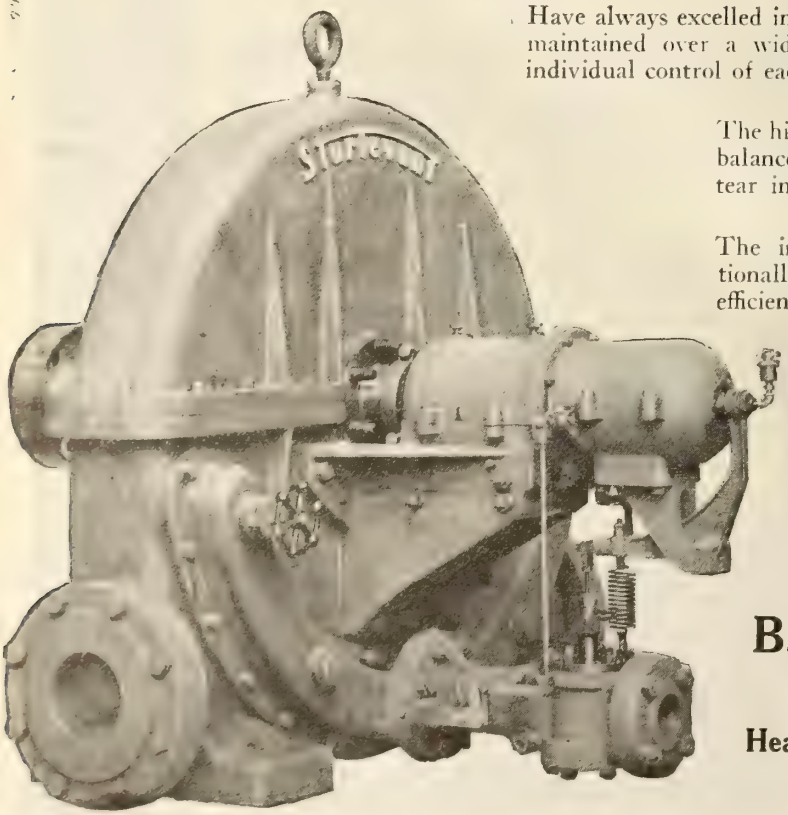
When the lesser attention and the large saving in oil are furthermore given due consideration it will be found that the turbine is actually the *more economical* of the two.

Sturtevant

(TRADE MARK)

Steam Turbines

Have always excelled in two points—supreme reliability and good economy maintained over a wide range in load due to superior design and the individual control of each nozzle by convenient hand valves.



The high grade of materials and workmanship plus careful balance insure smooth operation with minimum wear and tear in service.

The improverd governing mechanism maintains exceptionally close regulation, which particularly adapts these efficient turbines to direct connected generator drives.

Before deciding on your small turbine drives be sure to consult our engineers. They have valuable information to give upon request. Write for Catalog "V" today.

B. F. Sturtevant Company of Canada, Limited

Head Office and Works - Galt, Ontario

Sales Offices: Toronto and Montreal

in Operation

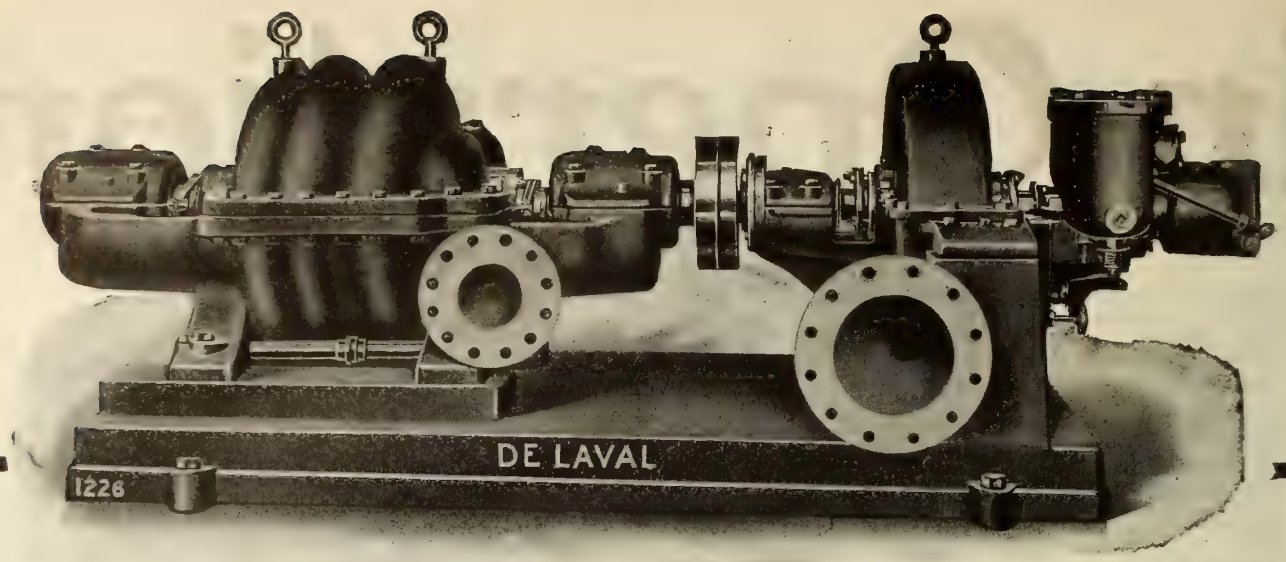
Sturtevant Turbines are particularly desirable for driving Boiler Feed and Condenser Pumps due to their dependability and smooth operation with practically no attention.

Sturtevant Turbines are protected from grit and dirt. This makes them ideal for direct connections to fans and blowers, where the latter are located in places where the dust would make it unsafe to operate an electric motor.

Sturtevant Turbo Generator Sets are very economical for small plants or for auxilliary equipment in the larger plants and central stations. The excellence of regulation is particularly commendable.

Sturtevant Gear Transmission can be supplied where the most efficient speed of the driver member is below the turbine speed.

In every case our engineers should be consulted before any Sturtevant Turbine Drive is specified.



A 13,000 H.P. Boiler Feeder

The De Laval Steam-Turbine-driven Three-stage Centrifugal Pump shown above has a capacity of 800 gals. per min. against 520 ft. head. This particular unit is used as a boiler feeder, and will supply 13,000 boiler h.p. normally.

De Laval Turbine-driven Centrifugal Boiler Feeders effect a great saving in space and in cost of supplies and attendance. There are no packings except the simple ones about the shaft, and no rubbing surfaces except the bearings, which are ring-oiled. There is no vibration and no pulsation in pipe lines, and automatic boiler feed regulators and feed water meters can give good results.

In smaller sizes De Laval Turbine-driven Boiler Feeders are combined in a single casing, with only two bearings, and one shaft.

Ask for our new Centrifugal Boiler Feed Bulletin N. 62.

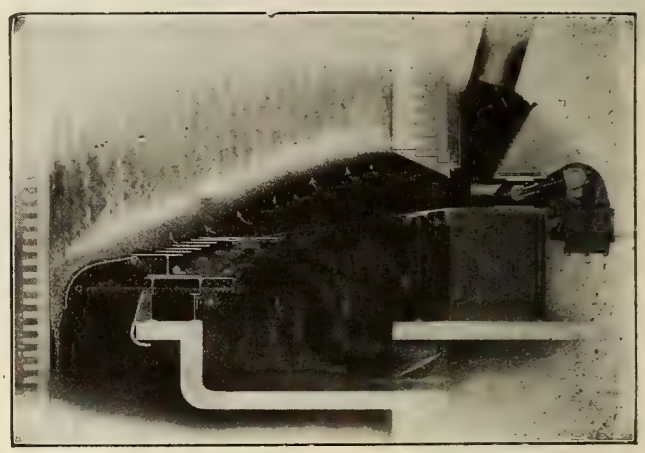
BURN ALL GRADES OF COAL



Cross-section Through Stoker Showing Automatic Operation

No device has shown itself better adapted to burn any available coal than the

RILEY UNDERFEED STOKERS

Low-grade coals—those high in ash—in sulphur and clinker-forming qualities—can be handled successfully for the following reasons:

1. The moving grates keep the clinkers broken up—combustion is intensified—the fuel bed is always active, even and in a homogeneous state.

2. The rocker dump, with its combination of vertical thrust and rocking motion, grinds up—discharges the ash continuously and automatically—keeps the fire clean and the bridge wall free from accumulations.

3. The underfeed feature makes possible high capacity and instant response to overload demands.

Our engineers will be glad to acquaint you with the wide range of fuels now being handled by the RILEY UNDERFEED STOKER under many varying conditions.

BAILEY METERS

BAILEY FLUID METERS record and integrate the flow of low and high pressure steam; boiler feed, condensate, circulating water, brine and other liquids; also compressed air, natural gas, coke oven gas, and practically any fluid at any pressure, temperature and capacity. Pressure and temperature records may be made on the same chart with the Rate of Flow.

BAILEY BOILER METERS accomplish more real results toward obtaining maximum efficiency and capacity than all other meters or instruments combined. They record Rate of Steam Flow from the boiler and Rate of Air Flow through the furnace; and the relation between these two records shows whether an excess or a deficiency of air is being supplied for the support of combustion. They may also record Flue Gas Temperature, Wind Box Pressure, Stoker Speed, etc.

BAILEY WEIR METERS record and integrate flow of water or other liquids through V-Notch weir; used for feed water, hot well discharge, or other fluids and chemicals at or near atmospheric pressure.

Write for Literature.

BAILEY METER COMPANY

Cleveland Ohio

What Would a 25% Increased Capacity Mean to You?

ELESCO Superheaters so decrease engine or turbine steam consumption as to provide a reserve boiler capacity and so make possible either the operation of your boilers at a lower rating, or the additional steam necessary to meet overloads.

In other words, ELESCO Superheaters make it possible to increase the power which a prime mover may develop over what it could produce with saturated steam.

This increased capacity may be obtained at one-fifth the cost of new boilers.

An increase in capacity as high as 25% is an opportunity worth investigating.

Send for Bulletin T-6, which tells where the ELESCO Superheater accomplishes these results.

Insure Constant Level

The most economic way to operate boilers is with constant water level and uniform constant inflow. With the level held constant at middle gage, the greatest amount of heating surface is presented to the hot gases and the maximum amount of steam space is available.

Vigilant Feed Water Regulators

meet these conditions in a very satisfactory way.

They are easily adjusted to maintain an absolutely constant water level at any arbitrarily determined height in boilers, and they feed continuously with perfect uniformity.

The De Laval Oil Purifier Insures Gears and Bearings

The De Laval Oil Purifier insures the power plant against losses and delays due to excessive friction, clogged oiling systems and all other troubles that result from the use of lubricating oil that has become foul.

It also insures plants against the trouble that is frequently caused by core sand, red lead, pipe scale and pipe burrs being present in the lubricating system.

All such impurities are instantaneously removed by centrifugal force in the bowl of the De Laval Purifier. It is the modern method of purification, and is rapidly replacing older and less efficient methods in well-equipped power plants.

The old method of allowing impurities to settle out of used oil by gravity effects only a partial purification, and is slow and wasteful of oil besides. Filters remove only the larger particles of foreign matter from the dirty oil, quickly clog up and become inoperative, and cause constant expense for new filtering material.

Compared with either of these methods, The De Laval Oil Purifier saves time, space and oil, and lengthens the life of machinery by providing oil free from all impurities.

It is a simple matter to install a De Laval Purifier in either an old plant or in one now building. It occupies less than two square feet of floor space, can be placed almost anywhere and is entirely independent of the other units in the plants.

You are invited to call on De Laval engineers for additional information and advice regarding your particular problem.

Write to nearest De Laval office for Oil Purification Bulletin No. 100; also Crank Case Oil Bulletin No. 102.

CONFIDENCE

—in yourself and in the tools you're using means efficient work.

Mechanics who use Starrett Hack Saws according to the Starrett Hack Saw Chart, are sure of their results. Starrett Saws are sold upon the *confidence* mechanics have in them.

A saw for each kind of material to be cut—each blade made of the finest grade of hack saw steel. And behind them the Starrett Service, helping hack saw users to get every bit of value out of Starrett Blades that we put into them. That's why they "cut quicker and last longer."

Begin to-day to lower your cost per cut. Write for "Hack Saws and Their Use," the first practical book on hack saws ever published.

The book that helps you lower your cost per cut"

For Quality Equipment

POWER PLANTS

We specialize in the design and construction of power plant equipment. Our engineers are prepared to investigate your problems and advise on the most economical machinery for your needs.

We can supply Corliss, Slide-Valve, Vertical, Horizontal, Simple and Compound Engines, and Water tube, Return tubular, Improved Scotch Marine, and Portable Boilers.

Robb Equipment is known to engineers and power plant superintendents for its long and dependable service, standard quality and modern design. When you are in the market—remember it will pay you to purchase equipment that has won the confidence of leading engineers.

The ANDERSON PRESSURE OIL FILTER

Makes Drip-pan Collected Oil as Clean and Pure as New

Though exceedingly high in price, over half the oil used is wasted—lost on wipers.

By placing drip-pans beneath the machinery and passing the oil thus collected through an Anderson Pressure Oil Filter, this waste can be practically eliminated.

The Anderson Filter cleanses and purifies the oil by a treatment identical to that of the refiners. It comes from the filter in a pure, clean state, fit for the finest bearings.

Write for fuller particulars.

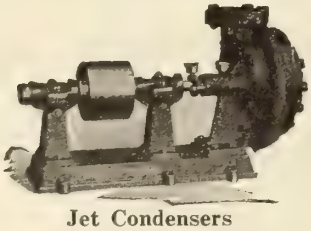
1935 West 96th St., Cleveland, Ohio

AMERICAN-MARSH PUMPS

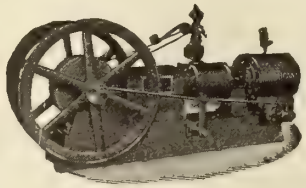
SIMPLE RELIABLE EFFICIENT

The American-Marsh steam pump is an improved form of the famous Marsh Pump which has been on the market for over thirty years, during which time over 150,000 have been manufactured and sold.

The American-Marsh Pump has no internal stuffing boxes, no tappets and no slide valves. The auxiliary valve is of the semi-rotative disc type of an improved design. The main steam valve is of the balanced piston pattern, assuring highest efficiency. The water ends have large valve areas and are fully bronze fitted, including solid bronze piston rods and bronze removable water cylinder bushings.



American-Marsh Centrifugal Pumps are made with the same high grade of material and workmanship which characterizes the construction of the steam pumps. They are made in all sizes up to 12 inch, both single and two stage for heads up to 250 feet.



The line also includes—

Power Pumps
Deep Well Engines
Air Compressors
Jet Condensers
Dry Vacuum Pumps
Boiler Feed Pumps

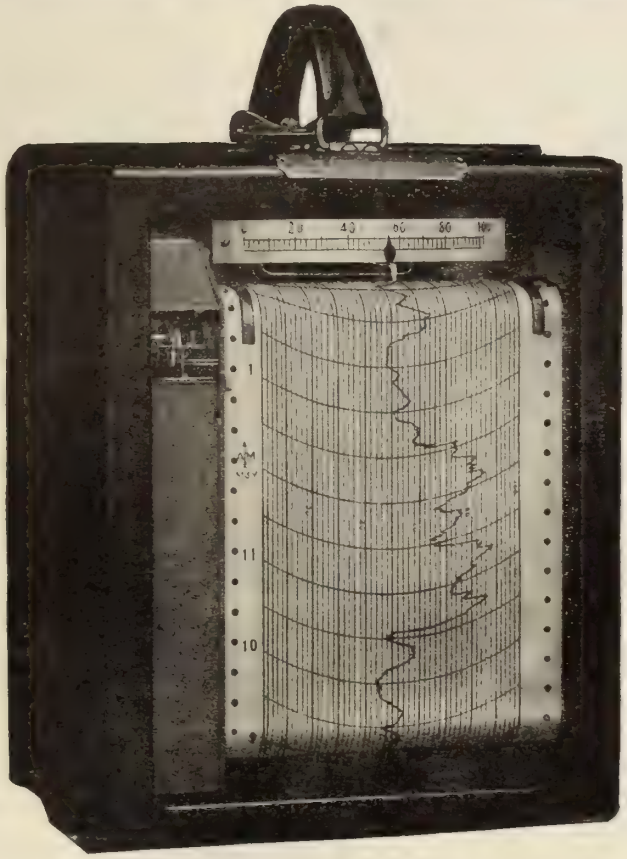
ESTERLINE

TRUE RECORDING INSTRUMENTS

Portable and Switchboard Types



Graphic Wattmeters **Graphic Voltmeters** **Graphic Power-Factor Meters**

¶ Ideal for generating stations, sub-stations, industrial and isolated plants where the value of a true load curve cannot be overestimated.

¶ The Illustration shows one of the Portable Graphic Meters, which is placed in an aluminum case with a glass face. The clock has an eight-day lever movement controlling the chart which is six inches in width and twenty-six feet long. A special inking device has been arranged for the marking of these charts. The holder will contain a supply for eight days and the ink is drawn through a tube to the pen by capillary action.

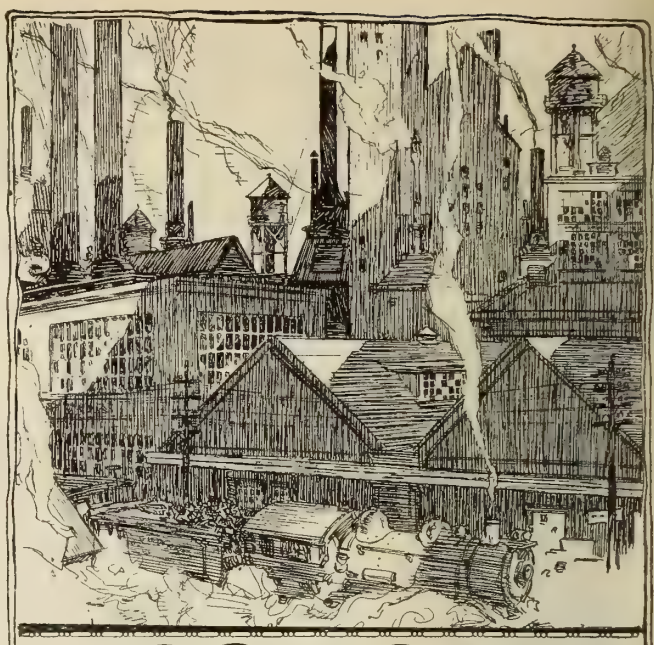
"No Seat to Leak"



ECONOMY *renewable* FUSES

Knife-blade type Economy Fuse

Industries persisting in the use of "one-time" fuses pay more for electrical protection than those equipped with Economy Fuses.

The famous Economy "Drop Out" Renewal Link makes possible an annual saving of 80% in fuse maintenance costs.

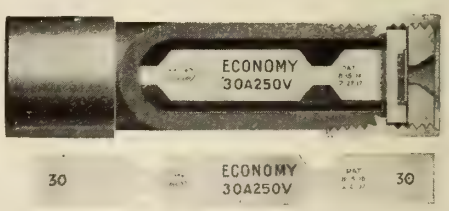
Nothing is destroyed when an Economy Fuse blows but the inexpensive strip of fusible metal.

This is quickly and easily replaced with a new "Drop Out" Renewal Link without delay to men or machinery. The heavy cartridge, end caps and the winged washers which lock the fuse are virtually indestructible and are used again and again.

Check up fuse costs in your plant. And remember that Economy Fuses give maximum protection at minimum cost.

For sale by all leading electrical jobbers and dealers.

Economy Fuse & Mfg. Co. of Canada, Ltd.
UNITY BLDG., MONTREAL, CANADA



Ferrule type Fuses with Economy "Drop Out" Renewal Link

Economy Fuses were the first line using inexpensive bare links for restoring blown fuses to their original efficiency to be APPROVED IN ALL CAPACITIES by the Underwriter's Laboratories.

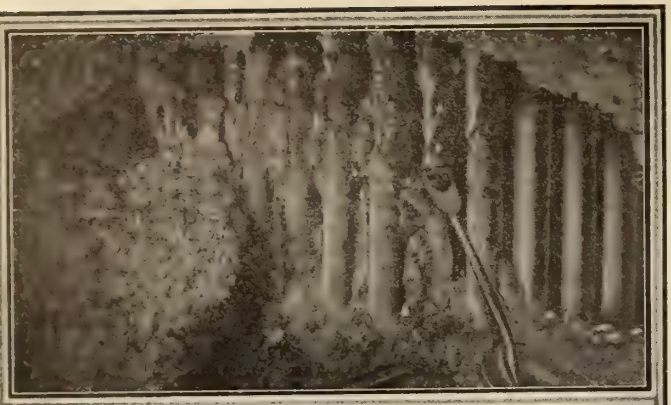
MONTREAL TORONTO



Can YOU Afford It?

Soot and ash deposits on the fire surface of boilers cause a loss of millions of dollars annually.

Your proportionate share in this loss depends upon the number of boilers you operate, the cost of coal, and the degree of cleanliness obtaining.

Suppose you have four 500 H.P. boilers. Normally these will require 4 tons of coal per hour, or 20,000 tons of coal per year on a 5,000 hr. basis. At present prices, this coal probably will cost you $100,000 per year.

If you customarily allow your boilers to get in the condition shown in the picture before cleaning them, your loss is anywhere from $10,000 to $20,000 or more per year.

If you clean your boilers regularly and conscientiously with the hand lance, your loss is from $4,000 to $8,000 per year, depending upon the skill of the fireman.

If you clean your boilers with Diamond Soot Blowers you incur no loss, but get value received in steam (within the limitations of your furnaces and boilers) for every dollar spent for coal.

Best of all, Diamond Soot Blowers cost but a fraction of the annual saving.

Ask for Bulletin 280.

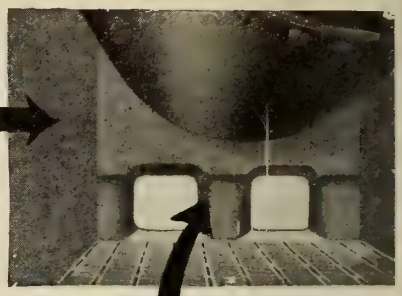
PLASTIC FIRE BRICK

Not a Brick or Joint in this Furnace Lining



For Water Tubes and Fire Tube Boilers of any type or make.

Door Arches Properly Formed and Flared Inward for the Easy Placing of Coal on Any Part of the Grate

THERE is no mystery about Betson's. It is the pioneer and proven Plastic Fire Brick that has made practical the one-piece furnace lining without joints, and is not affected by expansion and contraction. It is gastight and has a record of 20 years' satisfactory service under all sorts of trying conditions.

It comes in yellow-top barrels ready for use. Anyone can do the job. Experts not necessary. A mallet and trowel are the only tools required.

Write for booklet that tells of its uses in the boiler room.

Single Acting Simplex Feed Pumps
Compound Feed Pumps
General Service Pumps
Multiflow Heaters
Direct Contact Heaters
Evaporators
Distillers

The confidence-inspiring service which Weir Pumps are rendering their 65,000 users all over the world is ample proof of their merit. To watch their slow, steady, powerful strokes, is to become convinced that they are accurately designed and made to give long, satisfactory, efficient service.

In addition to our standard pumps, we have a large variety of designs for special duties. For high duty installations, for water or oil, we can supply special patterns, simple, compound or triple, for pumping against pressures up to 1,000 pounds per square inch.

Weir Service

To offer to our customers the entire resources of our organization—research, designing, manufacturing and operating—this is the Weir idea of service. The experience, the data and the results of our thirty years' concentration upon specific lines, we place at their disposal.

To serve our clients efficiently, satisfactorily and to the full extent of our ability —such is our aim.

The company of G. & J. Weir (Canada), Limited, has been incorporated to take over the business of the Clyde Engineering Company, Limited, and will manufacture their complete line of power plant auxiliaries and marine auxiliary machinery.

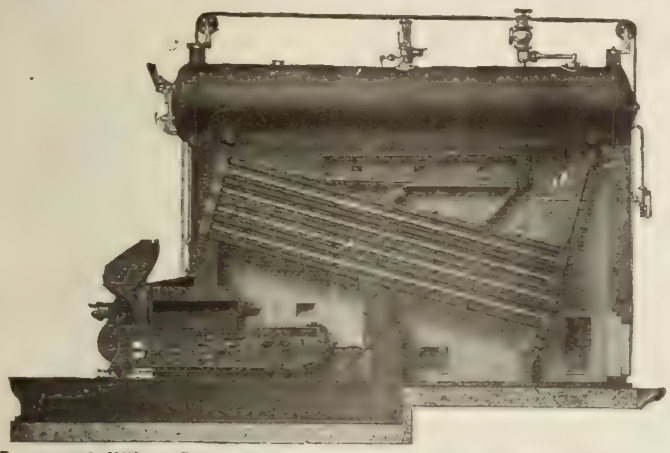
"ALL BRITISH"
"B.&W." PATENT WATER TUBE STEAM BOILERS

HIGHEST ECONOMY, SAFETY, DURABILITY. OVER 20,000,000 H.P. IN USE.



Babcock & Wilcox Patent Water Tube Steam Boiler, Superheater and Mechanical Stoker.

ALSO

Steam Superheaters
Mechanical Stokers
Coal-Handling Machinery
Piping, Feed Water Heaters
Water Softeners and Purifiers
and **ELECTRIC CRANES**

BABCOCK & WILCOX, Limited

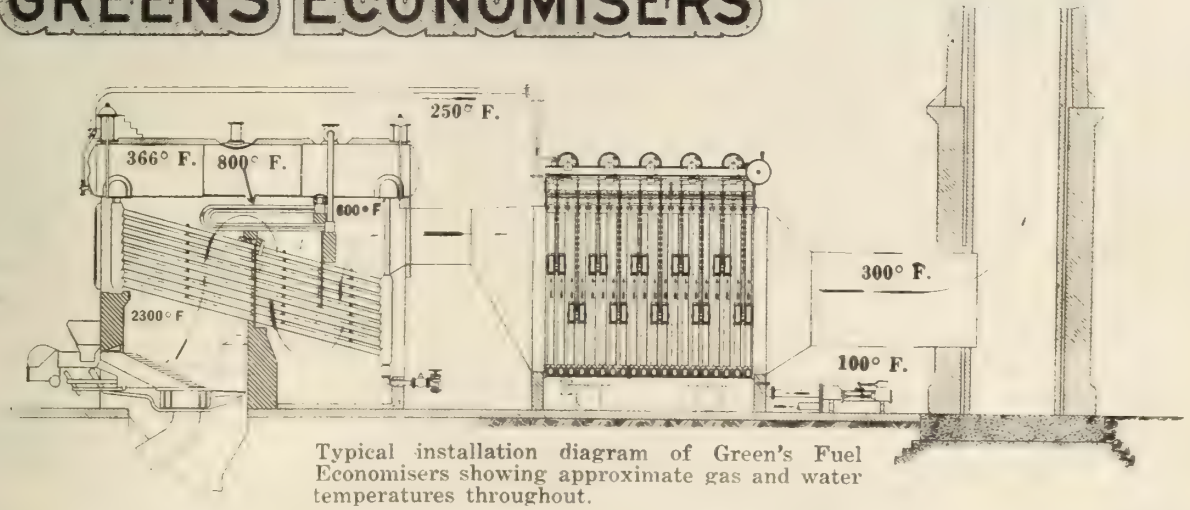
GREEN'S ECONOMISERS



Typical installation diagram of Green's Fuel Economisers showing approximate gas and water temperatures throughout.

At the recent Chemical Exposition in New York, during the fuel economy conference, one of the speakers, a noted engineer, stated that by far the greatest heat loss in the boiler room was in the sensible heat of the exit gases.
The use of extra boiler surface to cool gases below 500° F. does not pay because below 500° F. the heat absorbed per square foot of heating surface does not equal the cost of maintenance. The use of Green's Economiser is the most economical method for recovering this loss—it will reduce the gas temperature to a low figure at minimum cost by transferring the heat of the gases to the feed water, under boiler pressure, thus allowing the boiler to be supplied with water at a temperature slightly lower than the steam itself.

Write for our bulletin No. 151, or call for one of our engineers to inspect and make recommendations for your conditions.

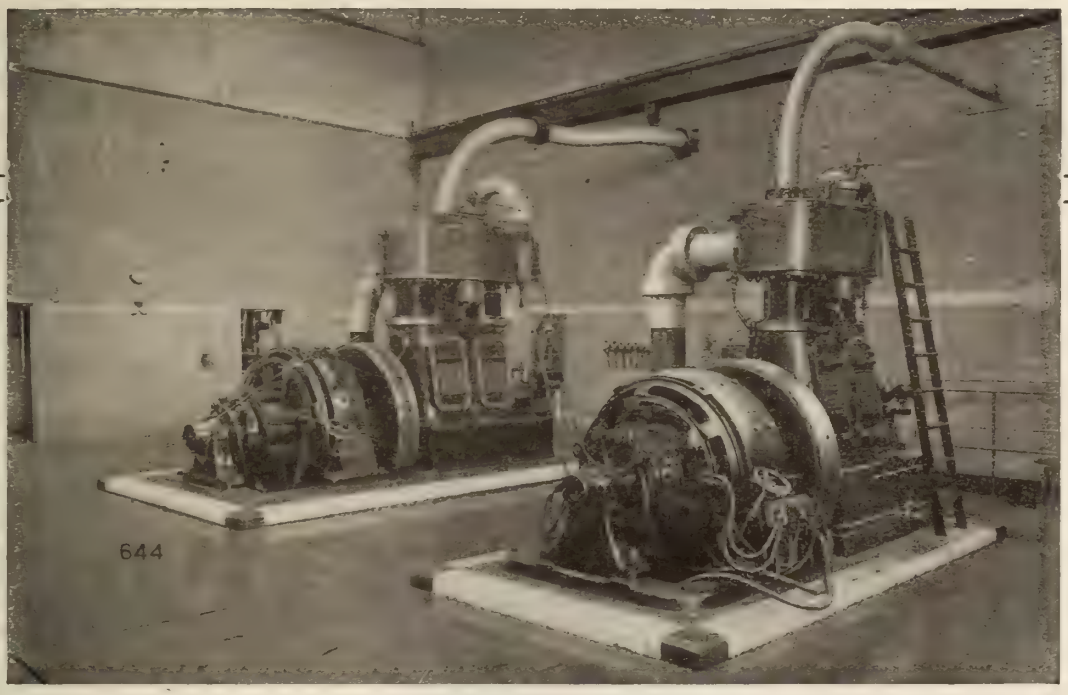
LIMITED
Engines and Air Compressors



Belliss & Morcom Engines installed in McGill University Power House
Total Horse Power, 1010 B.H.P.

Are you using your exhaust Steam ? Belliss engines are in use working against back pressures up to 190 lb. per square inch. In this way exhaust steam can be furnished to suit all heating requirements.

Write for Exhaust Steam Pamphlet.

Send us your enquiries for the following

Steam Engines
Gas Engines
Oil Engines
Diesel Engines
Steam Turbines

Air Compressors
Condensing Plants
Centrifugal Pumps
Boiler Feed Pumps

Pressure Filters
Gravity Filters
Water Softening Plants
Refuse Destructors

All enquiries carefully and promptly answered

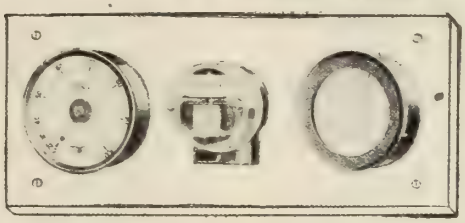
Republic TWINS

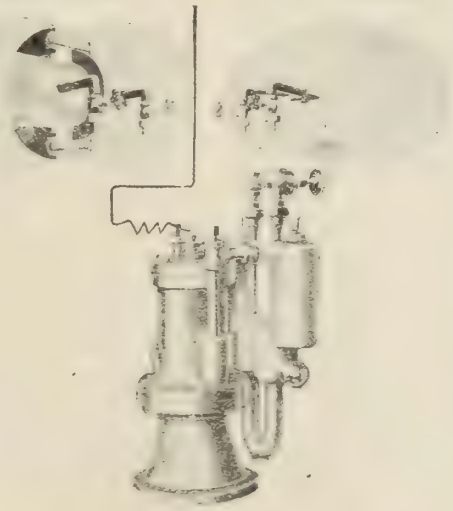
Trading Flow Meters for Boilers

BY installing Republic Flow Meters on a battery of six boilers, a well-known traction company avoided ordering two additional boilers to take care of its peak load. Not only was the cost of the boilers avoided, but also the continual expense of keeping additional boilers banked under light load during the off-peak part of the day. This Company traded Flow Meters for boilers at a tremendous profit.

When you consider that a saving like this is merely incidental to the many economies brought about by tracing erroneous conditions during the regular operation of the boiler room, you begin to realize how really indispensable an installation of Republic Flow Meters IS.

In every-day operation the Republic is a constant guide to furnace efficiency—a continual indication of the performance of individual boilers—an indisputable record of power costs by Departments.





Trading CO_2 Recorders for COAL

COMBUSTION means a combination of carbon with the correct amount of air. If too much air is admitted then coal is wasted. The only method of checking continuously and correctly is by the use of a CO_2 RECORDER. If a CO_2 Recorder is installed, the amount of air cut down, then the amount of coal is lessened; in fact, you have traded CO_2 Recorder for coal.

With coal at the prevailing prices, a CO_2 Recorder is a very good investment under such conditions.

Also by the use of a CO_2 Recorder **Black Smoke is avoided.**

Republic CO_2 Recorders have no valves, no glass (tubing or otherwise), only two moving elements, no complication of mixtures, absolute absorption insured by long travel of gases through absorbent.

NORWALK AIR & GAS COMPRESSORS

Specialization

The Norwalk Iron Works Company was first to use the compound principle of compressor construction in this country, and first, also, to give successful application to the multi-stage compression of air and gases.

Under the circumstances it was to be expected that the Norwalk Company would develop these fundamental principles of compression with exceptional success. The pioneer, by force of circumstances, becomes a specialist—and the specialist, in any field, is the party you wish to deal with.

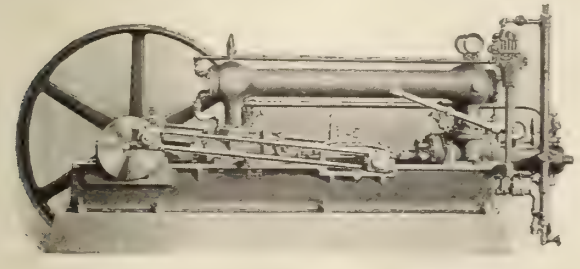
When contemplating the purchase of a Compressor for any branch of service—write us.

THE NORWALK IRON WORKS COMPANY

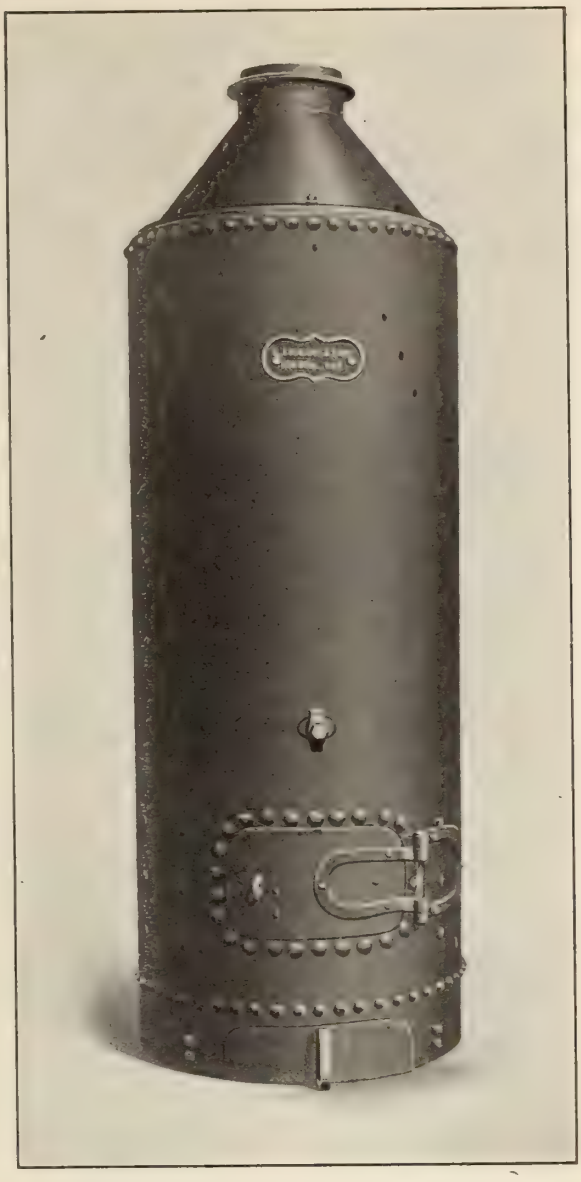
Pioneer Builders of Compressors

SOUTH NORWALK, - - CONN.

Canadian Sales Representative:
A. S. Leitch Company Toronto, Canada



A Norwalk Three-Stage, Belt-Driven Compressor for Oxygen. Also made for Hydrogen and Carbonic Acid Gas.



UPRIGHT BOILER WITH EXTENSION SHELL

We make the following types of Boilers:

Connelly Water Tube (*Patented U.S. and Canada*)
Return Tubular
Upright
Locomotive

We specialize in the making of

Smoke Stacks
Tanks of all Types
Plate work of any description
Grey Iron Castings

Head Office and Works: LONDON, CANADA

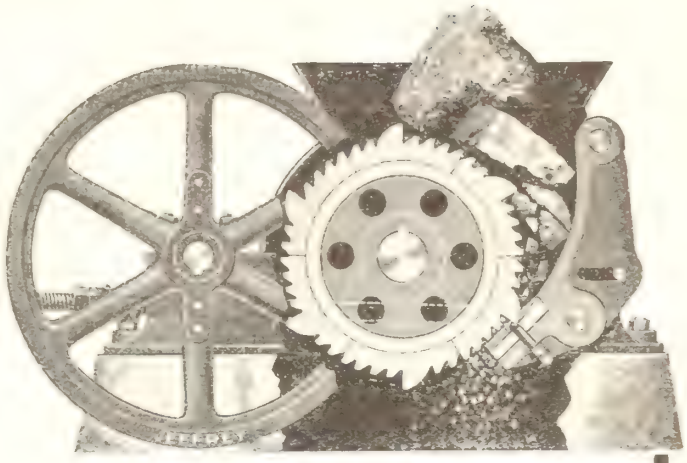
The Jeffrey Single Roll Crusher



Helps Solve Car Shortage

There is only one way to beat the scarcity on fine coal deliveries that is sure to come with the extraordinary car shortage that is now affecting the country, and that is to ***Crush Your Own Coal.***

Make yourself independent of mine and traffic conditions by installing a

Jeffrey Single Roll Crusher

right in your own plant.

Reduces run-of-mine or lump coal to stoker size in a single operation.

Rugged in design and construction, with cut steel gears, renewable segments, wearing shoes and bushings, accessible for adjustment, having a safety device, incapable of being choked—it consumes but little power, costs little, compact.

TRIMO

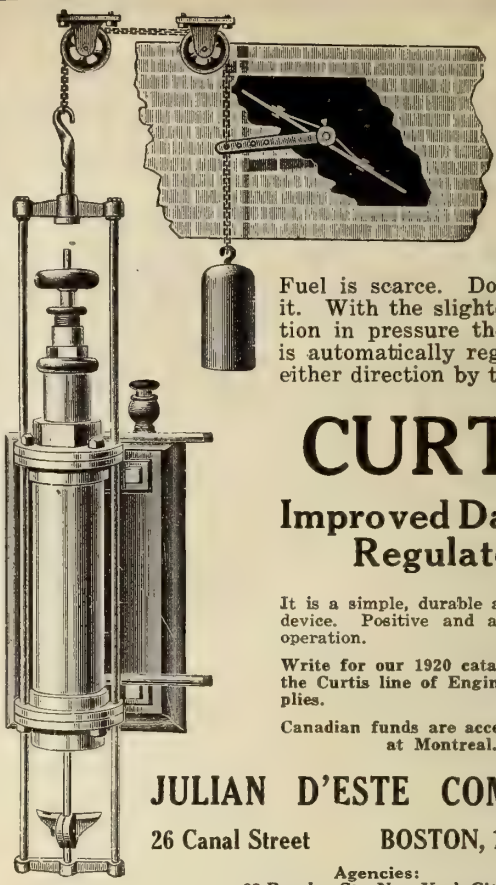
THE WORD TRIMO

Stands for good tools made by the Trimont Mfg. Co., which are the following:—

The Trimo Pipe Wrench
The Trimo Chain Pipe-Wrench
The Trimo Monkey Wrench
The Trimo Pipe Cutter (Hand)

The four good points that make **Trimo Pipe Wrenches** superior are the **Spiral Spring** always in place—**Steel Frames** that will not break—**Nut Guards** that protect adjustment nut — and the **Inserted Jaw** in handle that can be replaced when worn—**Save Money** and buy Trimo goods, made by

Trimont Mfg. Company
Roxbury (Boston,) Mass., U.S.A.



Save Fuel

Fuel is scarce. Don't waste it. With the slightest variation in pressure the damper is automatically regulated in either direction by the

CURTIS

Improved Damper Regulator

It is a simple, durable and effective device. Positive and automatic in operation.

Write for our 1920 catalog showing the Curtis line of Engineering Supplies.

Canadian funds are accepted at par at Montreal.

Uehling Instruments Stop Fuel Waste

Check FUEL WASTE

MOUNTAINS OF COAL and RIVERS OF OIL are wasted daily by burning fuel with incorrect air supply. Every pound of combustible material requires about 16 pounds of air. More than this means money wasted up the chimney, as the table shows. CO_2 in the flue gas is the tell-tale that enables your boiler operators to regulate air supply for maximum economy.

THE TELL-TALE OF FUEL WASTE

Lbs. Air per Lb. Combustible Burned	Per Cent. CO_2 in Flue Gas	Loss Up Chimney per Dollar Spent for Fuel	Needless Waste per Dollar Spent for Fuel
16	16	$.15	
21	12	.19	$.04
32	8	.28	.13
42	6	.38	.23
62	4	.56	.41

*Average practice in plants not equipped with CO_2 recorders.

UEHLING CO_2 EQUIPMENT

is inexpensive, in fact most plants are saving enough to wipe out its cost in a few months—some even in a few weeks. The Uehling system guides the fireman at the boiler while simultaneously recording results in the engineer's office.

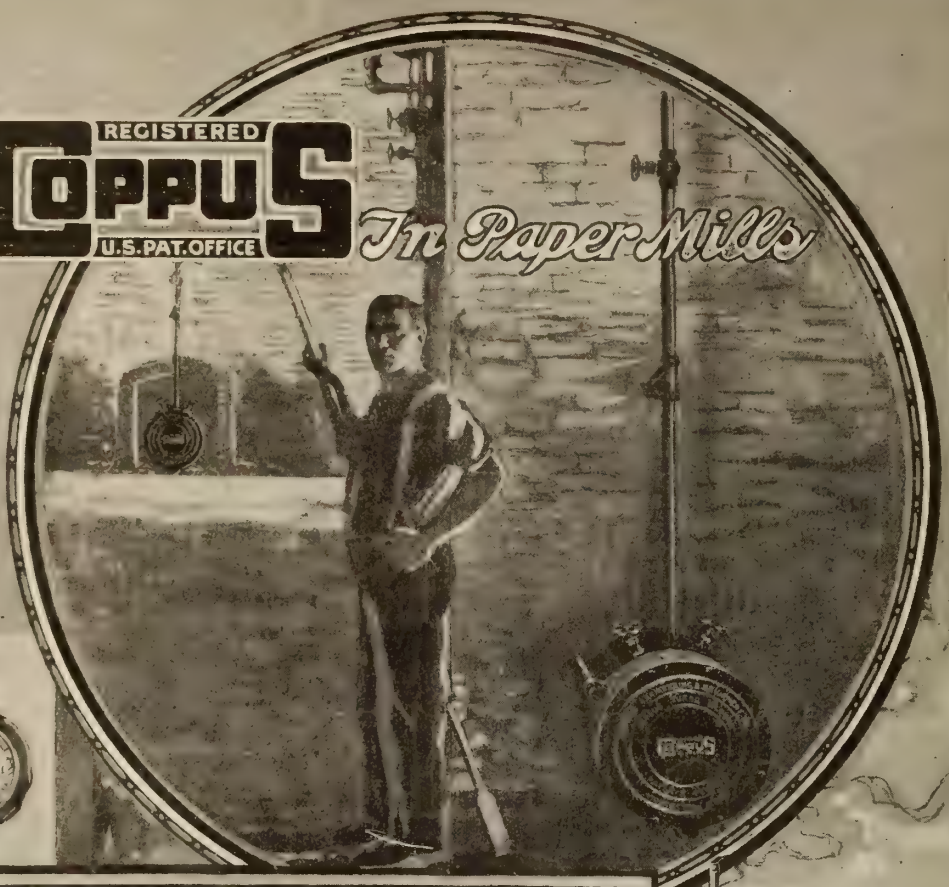
REGISTERED COPPUS U.S.PAT.OFFICE

In Paper Mills



STEADY steam pressure is a vital factor in making good paper. A sudden drop at the gauge might mean serious loss in the mill. Keeping up steam is a matter of prime importance.

That is why modern paper mills are equipping their power plants with COPPUS Turbo Blowers to maintain constant steam pressure under varying conditions of load, fuel, and weather.

For instance, the COPPUS Blowers shown above operating in the plant of the Hampshire Paper Company, makers of good paper, at South Hadley Falls, Mass., have kept steady steam pressure with very satisfactory results. Peak loads are quickly met, steam pressure is always constant, and cheap fuel is economically burned.

COPPUS Turbo Blowers are helping out engineers and speeding up boilers in power plants the country over. Their good work is not confined to the paper industry—it extends wherever power is used and coal is burned. If they are not already working for you it is likely that they could save time, money and labor in YOUR boiler room.

Write for Blower Catalog.

COPPUS TURBO BLOWER

WORTHINGTON
SPIROJECTOR CONDENSER

Utility and Economy are both served by Worthington

FOR installations of condensing machinery where first costs, economical maintenance and efficient performance are equally vital, Worthington Spirojector Condenser enjoys great favor.

Worthington Spirojector is of the syphon type with particular Worthington construction features that assure steady, perfect vacuum without aid of vacuum or dry-air pump. Air and non-condensable vapors are entrained and carried out by the falling water which is injected at opening below elbow in exhaust pipe and discharges as a rapidly descending spiral current of water.

Worthington builds all types of condensing machinery and since 1840 has developed a service and organization which is world-wide. Engineering service is freely tendered and carries with it no obligation to you.

WORTHINGTON PUMP AND MACHINERY CORPORATION
***Executive Offices:* 115 Broadway, New York City**
Branch Offices in 24 Large Cities

Other Worthington Products:
Steam, Power and Centrifugal Water Works Pumps. Meters, Oil Engines, Condensing Machinery, Air Compressors, Vacuum Pumps and Water Wheels.

To further enlarge their service, Worthington have acquired the good-will and mechanical equipment of the Platt Iron Works, Dayton, Ohio, for manufacturing Oil Mill Machinery, Hydraulic Turbines, Feedwater Heaters and High Pressure Air Compressors.

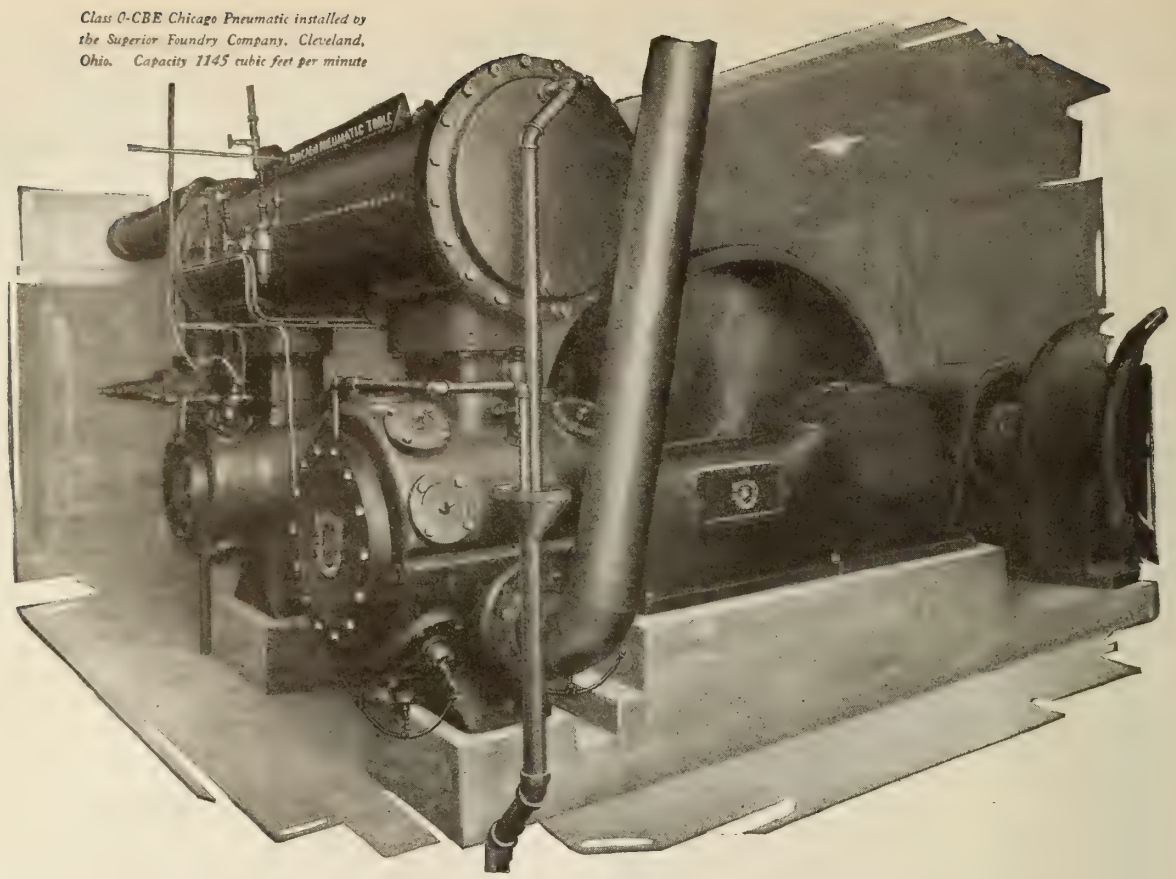
POWER HOUSE, November 20, 1920. Vol. XIII., No. 22. Published semi-monthly at 143-153 University Ave., Toronto, Canada. Subscription price in Canada, $2; in United States, $2.50. Entered as second-class matter at the Post Office Department, Ottawa, Canada. Entered as second-class matter July 1, 1912, at the Post Office at Buffalo, under the Act of March 3rd, 1879.



Class O-CBE Chicago Pneumatic installed by the Superior Foundry Company, Cleveland, Ohio. Capacity 1145 cubic feet per minute

"A man's services are of value in proportion to the amount of supervision he requires"

AIR COMPRESSORS, like men, are worth most that require least supervision.

Power input, lubrication and air output of Chicago Pueumatic Air compressors are automatic—conserving both driving power and man power under all loads.

Other C-P features that insure further productive efficiency are—Simplate flat-disc indestructible valves, exceptionally large bearing surfaces, totally enclosed frame construction, and unusual simplicity of construction and operation throughout.

These features are embodied in over 300 distinct types and sizes—an air power unit to fit *your* purpose with least supervision.

HEAVY service imposes a tremendous strain on your plant machinery. Every individual part of every unit must be properly lubricated to carry the load.

Scientific selection of your lubricating oils is every bit as important as the careful choice of mechanical units themselves.

Imperial Lubricants, backed up by Imperial Service, will solve your lubricating problems. Increased production, minimum depreciation and lowered lubricating costs surely follow.

There's a right grade of oil for every service condition; the quality is always uniform, with ample supplies conveniently available. Imperial Lubrication Engineers will gladly advise you on all lubricating problems.

The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.**

BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.

Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

QUALITY YORK SERVICE

York Uniflow Engines for Ice Making and Refrigerating Plants

One of the most important considerations in an Ice Making or Refrigerating Plant is the type of prime mover. An economical ice plant should have a dependable motive power, and one which will maintain a reasonable economy when called upon to operate over a range of from ¼ to 1¼ times the normal load.

It is well known among refrigerating engineers that the best compressor economy is obtained when evaporating pressures are carried as high, and condensing pressures as low, as possible. Even well balanced plants are forced to meet extreme seasonal conditions, with evaporating pressures varying from 20 to 30 pounds and condensing pressures from 85 to 225 pounds. These pressure variations and seasonal requirements of the Trade impose load factors of corresponding variation on the engine operating the compressor.

The Uniflow Steam Engine presents itself as the best solution of this difficulty

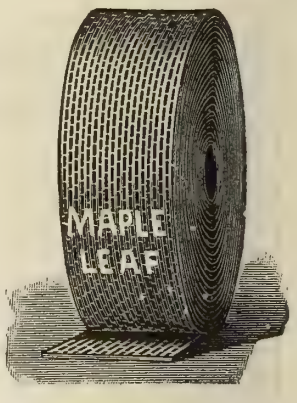
Dominion Belting Company, Limited
Hamilton, Canada

Sole Manufacturers of the celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing.

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.



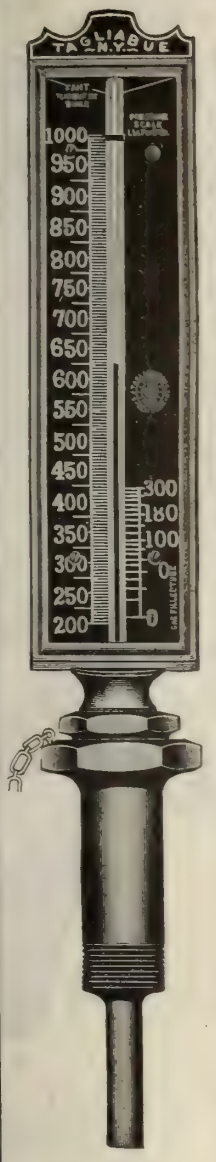
"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber or Balata, as well as our own make.

Write us for prices, and if desired we will be pleased to furnish samples and further information.

A trial order will convince you of their utility.

DOMINION BELTING CO. Ltd., Hamilton, Canada-Quebec Branch: 51 Duluth Bldg., Montreal



TAG

POWER PLANT THERMOMETERS INDICATE THE EXACT HEAT *INSTANTLY*

Getting *instantly* the exact heat indications of live or exhaust steam isn't possible with ordinary power plant thermometers.

Because all instruments haven't the required sensitiveness that eliminates every sluggish tendency. All do not everlastingly indicate true temperatures, regardless of time and constant use.

But with TAG Power Plant Thermometers, pre-precision is guaranteed *permanent*—due to the TAG method of scientific construction.

The special annealing process seasons the glass bulb for all time, preventing shrinkage and assuring extremely correct indications. The graduations intervals are individually marked according to the particular application.

TAG Power Plant Thermometers faithfully indicate the exact heat instantly—and our positive guarantee protects this unfailing service.

No Stoker is Better Than its GRATES

Back of every feature of MURPHY GRATE construction are *many* sound reasons. Consider how these features save you dollars—in fuel—in labor—in maintenance.

The long—narrow—but deep sections give eighteen to twenty-eight square inches of cooling surface to every inch of exposed grate surface.

The liberal air space (47% to 52%) gives double the capacity of the boiler "without one penny for draft."

The correct proportion and distribution of ribs on the stationary grates, combined with the greatest accuracy of machine moulding have solved the sifting problem.

The continuous movement of the ribless grates ¾" above and ¾" below the surface of the stationary grates—breaks up the fuel bed — prevents avalanching — keeps the grates clinker-free—and advances the ash gradually to a point where it is removed by the clinker grinder. It is this action that gives the Murphy Furnace the faculty of ***burning anything that has heat in it.***

Yet with all these advantages, the Murphy Grate of to-day is built to the same policy that has characterized every improvement. First, to make all parts standard; second, to make every piece interchangeable; third, to advise users of new developments so that they may keep their equipment up to date---and operating at top-notch efficiency.

For information on the Riley Underfeed Stokers for large boilers, see February 5 advertisement or send for Riley Stoker catalog HR-11.

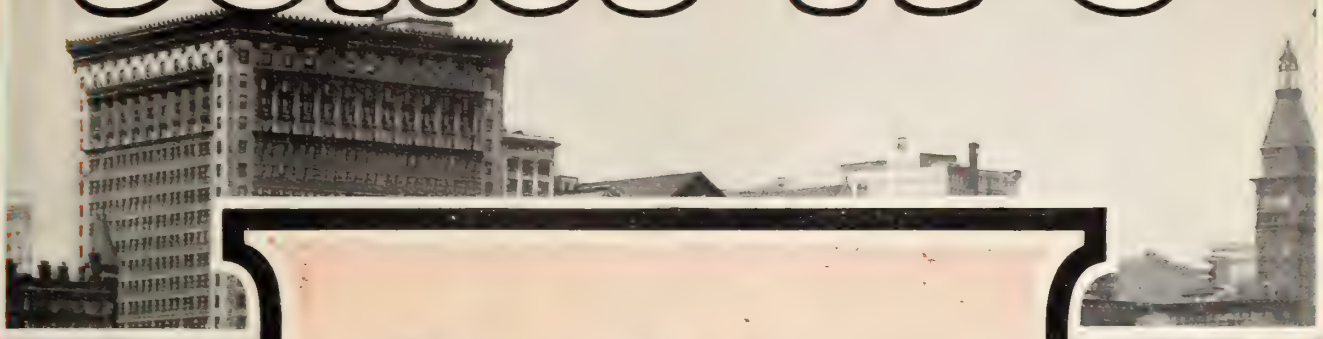
Jones "A-C"

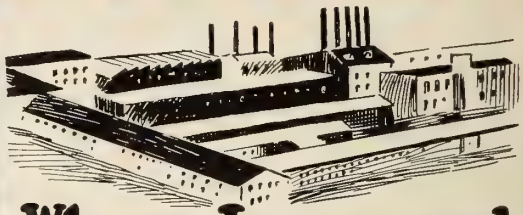


The Stoker for Every Load and Every Fuel

Which Is

Where the Peak Load is the Rule

Canadian Central Stations and Public Utility Plants in general will find the Jones "A-C" exactly suited to the fluctuating load. The automatic control of fuel and air in the Jones "A-C," and individual control of retorts provide unequalled flexibility. From banked fires to 300 per cent. of boiler rating in a very few minutes is typical Jones performance.



Where Increased Production Calls for Continuous Over Loads

Large Canadian Industrial Plants operated at peak capacity will find the ability to operate continuously a marked advantage. The "automatic-cleaning" feature of the Jones "A-C" and the extreme simplicity eliminating shutdowns, permit continuous operation at high capacity. Two hundred per cent. of rating for 24 hours a day is regular practice in many Jones-equipped plants.

Your Plant?

Where Smokeless Operation Ranks First

The Jones "A-C" is the ideal stoker where rigid smoke ordinances are in force. The under-feed principle of combustion, as originated and perfected in the Jones Stoker, insures smokeless operation. In the words one Jones user, "We have boosted our load from 150 per cent. of rating to 340 per cent. in eight minutes without visible smoke."

Where Only the Lowest Grades of Fuel are Available

The smaller isolated plants, limited to a single fuel diet, offer a great field for the Jones "A-C." The Jones "A-C" insures complete combustion of the lowest grade fuels, and permits the firing of high-ash coals without clinker trouble. Bone coals containing as high as 41 per cent. ash have been burned efficiently.

Saves Coal for Plants of Every Type and Size

TO-DAY stoker firing is an acknowledged economic necessity—not alone stoker firing, but *high duty stoker firing*.

Hand firing is being discarded in Canadian plants because with present-day coal and labor costs, plant owners have found they can no longer afford hand firing.

If you cannot afford hand firing, you cannot afford to be without the *highest duty* stoker, the Jones "A-C."

The stoker that combines the fundamental advantages of all types, while sacrificing the incidental advantages of none, is naturally the best for any plant.

It is because the Jones "A-C" (Automatic-Cleaning) Stoker has had the advantage of 25 years of development by an organization comprised entirely of engineers—because our experience has covered every conceivable variation of load and fuel condition because the under-feed principle, originated by this Company, has become universally accepted, that we claim the Jones "A-C" to be exactly such a stoker.

Your stoker firing problem probably falls within one of the four general classes described above. Since the Jones "A-C" meets not only the requirements of your plant, but of any plant, you equip not alone for the present, but for any possible future condition as well, when you install the Jones "A-C."

JONES STOKER

IN installing the new Jones Automatic-Cleaning Stoker, this Company will draw on the greatest fund of engineering facts ever placed at the disposal of Canadian power users.

The accumulation of twenty-five years of stoker firing experience, which has made possible the Jones "A-C" Stoker, is available for the solution of the stoker firing problem of the individual plant.

The combined engineering resources of two companies which have long been famous for comprehensive service is now massed behind a stoker which after three years of severe test in some of the most modern and progressive plants in the United States has been acclaimed the greatest single stride ahead in the entire history of stoker firing.

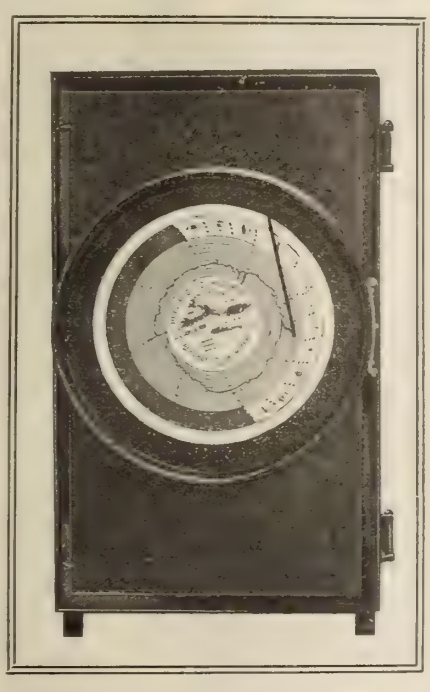
The alert engineer will make profitable use of this broad engineering service.

The Under-Feed Stoker Co. of Canada, Limited

81 Victoria St., Toronto

Republic

CO_2 RECORDER



Think of the Price You Now Pay For Coal

You Can't Afford to Waste It!

UNLESS your firemen know exactly every minute of the day the conditions of their fires, waste of fuel invariably follows. They should know precisely what changes in firing, coal feed or air supply are necessary, in order to secure maximum results. Guesswork won't do—not even the guesswork of the most experienced operators. There is but one safe way. That is by placing reliance upon a CO^2 Recorder of Proven Merit.

The "Republic" is Proving its Worth To-day in Many Plants

Furnaces in these plants are giving neither too much, nor too little air. What's the result? They are burning less coal and securing higher efficiency. This is easily explained:

In order to evolve the total amount of heat contained in the fuel, it is necessary that each atom of carbon (C) should unite with two atoms of oxygen (O_2) to form the compound known as carbon dioxide (CO_2). If the supply of air is insufficient and there is not enough oxygen to combine with the elements of the fuel, some atoms of the carbon will combine with only one atom of oxygen and will escape in the form of carbon monoxide (CO). This combination produces only about one-third of the heat in the fuel, while the other two-thirds remain in the carbon mon-oxide compound which is escaping in the waste gases.

If the supply of air is more than necessary for the complete combustion of the fuel, the excessive amount of free air passing through the furnace carries enormous quantities of heat with it up the smoke stack. An excessive supply of air usually results in the greatest loss of fuel in the furnace.

The REPUBLIC CO. RECORDER has been developed to operate continuously under all boiler room conditions. The operator is enabled to observe the conditions of combustion at all times and to obtain the highest efficiency WITHOUT WASTE OF FUEL!

Bulletin No. 9 contains valuable information. May we send it?

POWER HOUSE

Members of the "Audit Bureau of Circulations"

The Power Plant Journal of Canada

Published in Toronto

Established 1907
Published Sem-Month

A Series of Articles on Power Plant Management

This Article Deals With the Various Conditions of Boiler Operation Requiring Natural, Forced or Induced Draft, With the Considerations Influencing the Choice of Either

By ROBERT JUNE

THE attainment of high efficiency in the combustion of fuel is, to a large extent, dependent upon proper draft regulation. If there is no draft, combustion cannot take place. If there is insufficient draft, an immense amount of fuel is wasted and the boilers will not produce enough steam to meet plant requirements. If there is too much draft, you heat all out doors with the B.t.u.'s emitted from your stack. So you must have draft and you want just the right amount.

The ideal draft enables the boiler to carry the full load, while producing the highest practicable percentage of CO_2, and the lowest percentage of CO in the uptake gases. This ideal draft naturally varies with the individual plant, and with changing conditions in the boiler room. Among the factors which determine the amount of draft required are kind and grade of fuel, design of furnaces and grates, and in particular the rating at which the boilers are driven. Thus, other things remaining constant more draft is required to produce 20,000 lbs. of steam an hour from a boiler than to produce 10,000 pounds.

A consideration of the facts just recited leads inevitably to the conclusion that every boiler should be equipped with a draft gauge. You must find out what the proper drafts are for different loads and other varying conditions on your boilers, and then see that exactly the required drafts are supplied. It is not our present purpose, however, to discuss draft gauges, but rather the means of supplying the pre-determined drafts.

Before starting our discussion let us define the term "draft." Ordinarily this word is applied to two different conditions: First, the difference in head or pressure available for producing motion to gases; the second, the actual motion of gases themselves without regard to pressure. We will ignore this second meaning, and use the word "draft" as denoting the difference in density and pressure of the gases and air at various points.

Natural Draft

Forty years ago, nature alone was used for furnishing draft for furnaces. Since the weight of the column of hot gases in the chimney is less than the weight of an equal column of the cooler outside air there is produced at the grate a difference in pressure which forces the hot gases up and out of the chimney.

With natural draft the chimney has to do three essential things:

1. Draw the air through the grates and fuel bed.
2. Draw the gases through the setting and tubes.
3. Draw the gases through the breeching to the stack.

With free-burning bituminous coal at moderate rates of combustion, the draft required for operations No. 2 and No. 3 may be approximately equivalent to the draft required for operation No 1. However, if the coal is of poor grade, considerably more draft may be required for No. 1 than for Nos. 2 and 3. As a matter of fact, with fine anthracite, we may require five times as much draft for operation No. 1 as for the others. This means that our chimney must be designed to take care of operation No. 1, whereas, with the use of mechanical draft, we can reduce considerably the functions of the chimney for this particular operation.

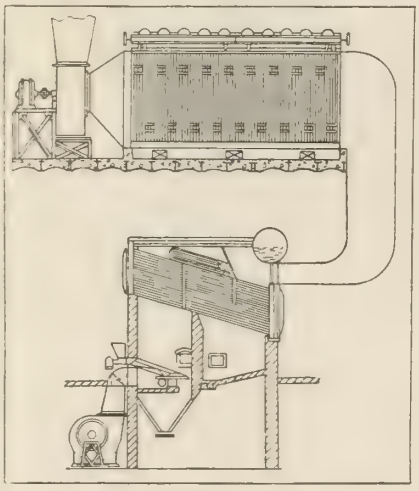

FIG. 1.

With natural draft, every time the fire door is opened a blast of cold air is drawn in which scrubs the tubes and boiler shell, placing strains on the metal and furnace walls, decreasing the rate of heat absorption and cooling the fire. In addition the gases are "short circuited," the strong suction pulling them through the boiler at high velocity, so that they take the shortest path to reach the stack, and come in contact with only a portion of the tubes and shell, so that they leave the boiler with much of the heat in them which they would give up, if made to pass through with lower velocity.

The draft produced by a stack depends mainly upon its height and the temperature of the uptake gases. Chimneys should always be designed to meet the maximum requirements, permitting the damper to be closed at times. There is usually no practical means of increasing natural draft per se after the maximum has been reached. It must also be remembered that natural draft is particularly susceptible to atmospheric influence and may be seriously impaired by adverse winds.

Mechanical Draft

In view of the limitations of natural draft it is not surprising to find that in many cases mechanical draft possesses very great advantages and under certain conditions is indispensible. Mechanical draft is very flexible and readily adjusted to effect various rates of combustion.

Among the advantages of mechanical draft are:

1.—It costs far less to install a compact and efficient mechanical draft system than it does to lay foundations and build a great chimney.

2.—It makes possible any percentage of overload, thus going far beyond the limits of chimney draft. It is not at all unusual, with a properly designed mechanical draft equipment, to develop from 125 per cent. to 225 per cent. of the rated output of the boilers. If underfeed stokers are used, much higher overloads can be carried. The mechan

ical draft system of handling peak loads is usually found more desirable than the method of installing sufficient rated boiler capacity to take care of the maximum peak loads, and it has found especial favor in those plants which are forced to take care of high peaks during short periods of the year, as well as those which run at continuous heavy overloads.

3.—Inferior and cheap grades of coal which require a strong draft can be burned efficiently. Thus, the installation of mechanical draft at times makes possible the substitution of a cheap coal for a more expensive one.

4.—It is independent of climatic conditions.

5.—It assures individual draft control of each boiler, thus enabling operators to meet the requirements of complete combustion under existing conditions. This is very important. With natural draft the boiler nearest the stack receives more than its share of the draft, and the boiler farthest from the stack gets much less than its share, hence rendering accurate individual draft control of the various boilers very difficult, if not impossible.

6.—It enables operators to get up steam, or take on heavy overloads very quickly.

7.—Short circuiting of gases is eliminated, as a boiler may be operated with a partially closed damper. This makes the entire heating surface of the boiler effective, increases the production of steam, and prevents strains due to uneven temperatures.

8.—Where with natural draft, manufacturing losses would result from the shutting down of one or more boilers such losses can be eliminated by the use of mechanical draft which permits increasing the output of the remaining boilers.

Types of Mechanical Draft Equipment

Mechanical draft may be produced by any one of three distinct systems:

1.—Vacuum or induced draft.

2.—Forced draft.

3.—Balanced draft.

With the first or induced draft systems, a partial vacuum is created above the fire, the effect being similar to, but more pronounced, than natural draft.

Forced draft is produced by pressure developed in the ashpit, the effect being to force air through the fuel bed.

Balanced draft is a combination of forced and induced. Forced draft is used to drive the air through the fuel bed only. Beyond this point, induced draft is depended upon to create a suction throughout the furnace and setting. The adjustment, or balance, is such as to provide for practically atmospheric pressure in the combustion chambers, an extremely desirable condition.

Induced Draft

The earliest form of induced draft consisted of the application of jets of live steam over the fuel bed or at the base of the stack. Tests have shown these jets to consume from five to eleven per cent. of the total steam generated. They are extremely wasteful and should be tolerated only in plants where boilers need to be forced for very short and infrequent periods.

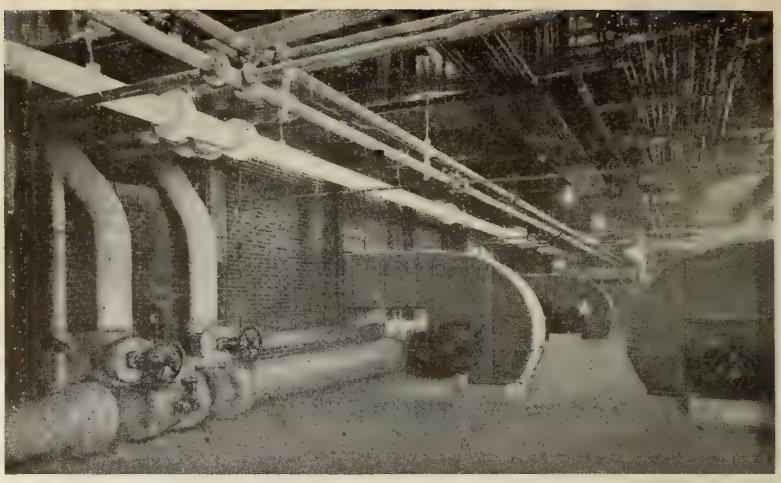

FIG. 2.

In the modern plant, induced draft is produced by means of a fan, the suction side of which is connected with the uptake or breeching of the boiler or batteries of boilers. The products of combustion are usually exhausted through a stub stack. In a typical installation, two fans of the duplex type are placed above the boiler setting. A by-pass is usually provided so that the fan can be cut off entirely in case of accident or when mechanical draft is not required. Since the induced draft fan handles hot gases it must, under average conditions, have a capacity approximately double that of the forced-draft fan which delivers cold air, but at the gases of lower density the power required per cubic foot handled is less.

The advantages of induced draft over forced draft are very pronounced. Among the advantages are:

1.—With induced draft, fires will burn evenly all over the grates; there is no trouble from holes or patches burning in certain parts of the fuel bed, as with forced draft unless carefully watched.

2.—It is never necessary to shut off the draft when firing, as there is no pressure in the combustion chamber to force scorching gases and dust out of the firing doors when opened. The ashpit can be cleaned any time without shutting off the draft as at all points the flow is toward the place at which the greatest suction or depression in pressure prevails this, of course, being within the induced draft.

3.—The ventilation of the boiler-room is better, as the air is drawn into the furnaces from the boiler room, and is replaced by fresh air from the outside, whereas with forced draft, there is a tendency for smoke and ill-smelling gases to escape through crevices in the boiler setting and through leaks in the flues, especially when the path of the waste gases to the atmosphere is restricted by economizers.

4.—The boiler flues can be kept cleaner as there is less lifting effect at the fire and consequently ashes and dirt are not carried in suspension and deposited in places where the velocity of the gases is lowered, to the same extent as is the case with forced draft.

5.—With induced draft, very much larger fuel economizers can be used, as the temperature of the gases can be reduced to a very low point, enabling a large percentage of the heat leaving the boiler to be recovered without bad effects.

Induced draft can be used with all kinds of fuel and it is adapted to ordinary grates, rocking grate bars, chain grates and other types of furnaces except those in which underfeed stokers and hollow blast grates are employed.

An induced draft plant costs considerably more than a forced draft, on account of the larger fan required, but the operating expenses are but little greater. With a boiler plant of 1,000 horsepower, or more, the cost of a single induced draft fan, engine, stack, etc., will approximate from 40 to 50 per cent. of the outlay required for a brick chimney of equivalent capacity, and the double-fan outfit will approximate from 50 to 60 per cent. The double-fan system is particularly adapted to plants which operate continuously and where even a temporary break-down is a serious inconvenience.

Forced Draft

Whenever the greater portion of the resistance offered to the flow of air is encountered in the furnace, it is advisable to use forced draft. Forced draft is created by the development of pressure in the ashpit through the agency of a fan or turbo-blower. The most approved method is to pass the air through the bridge-wall, thence toward the front of the grate, though it may enter through an underground duct or through the side of the setting. Forced draft is usually adopted in old plants where increased demands for

power require that the boilers be forced far above their rating to save the heavy expense of new boilers, or in plants burning refuse, anthracite culm or screenings, which require an intense draft for efficient combustion. Forced draft is also well adapted for underfeed stokers of the retort type, hollow blast grates, and the closed fire-hole system. The air supply may be taken from an air chamber built around the breeching, thereby supplying the heated air to the fan and effecting a lower temperature in the breeching and a higher temperature in the furnace. The objection is sometimes raised against forced draft that the gases tend to pass outward through the fire door when the fire is cleaned or replenished, since the pressure in the furnace is greater than atmospheric. This objection may usually be overcome by suitable dampers in the blast pipe which are closed on opening the fire doors, or by having sufficient stack action to create a partial vacuum in the combustion chamber. With a boiler plant of 1,000 horsepower, or more, the cost of a forced-draft fan, engine and stack will approximate from 20 to 30 per cent. of the outlay for an equivalent brick chimney. The power consumption will depend upon the character and efficiency of the motor or engine and will range from 1 to 5 per cent. of the total capacity.

In recent years there has been a very marked increase in the use of turbo-undergrate draft blowers, in place of the forced draft fan. Turbo-blowers are installed in each setting. They consist essentially of small impulse steam turbines directly connected to special design propeller fans fixed in the side walls of the setting. The fan discharges below the grate and may be automatically controlled by damper regulation. The turbine exhaust may be discharged into the ashpit to prevent clinkers, or it may be used in the feed-water.

Turbo-blowers are the least expensive of all kinds of mechanical draft to instal, and their ease of regulation is a point which commends them very much to the average plant engineer.

Types of Fans

Centrifugal fans used with either forced or induced draft may be divided into two general classes; those having rotors with a few straight or slightly curved blades of considerable length, commonly designated as steel-plate fans; and those having rotors with a number of short curved blades, generally known as multi-vane fans. In general the multi-vane fan is more efficient than a steel-plate fan, as ordinarily constructed, and requires less space than the latter for equal capacity and efficiency. Another important advantage lies in the fact that the higher speed of the multi-vane fan permits of direct connection to high speed prime movers. The steel-plate blower, however, is not necessarily a low efficiency device since by special design it may be made to give higher efficiencies than obtained from the curved short blade construction In small plants the power requirements for mechanical draft systems are low and the type of fan has but little effect on the over all cost of operation, but in large central stations the power requirements are considerable and the type and attending pressure characteristics greatly influence the ultimate economy.

FIG. 3.

Balanced Draft

In the balanced draft system a uniform pressure, nearly atmospheric, is maintained in the furnace for all rates of combustion. In actual practice, this ideal condition does not obtain, the pressure of the furnace gases being slightly below that of the atmosphere.

To maintain atmospheric pressure in the furnace, natural draft cannot be used, but instead a system of forced draft is utilized which gives a constant volume of air at variable pressure for a given speed of the blower, the pressure being controlled automatically according to the resistance of the fuel bed.

There are several ways in which this may be done. One method consists of a damper in unison with the varying speed of the blower that supplies the air to the furnace, the speed of the blower in turn being varied by the steam pressure. Another method, and the more preferable, is by using a furnace pressure regulator controlled by the pressure of the gases in the furnace chamber. When a change of gas pressure occurs the damper regulator operates the flue damper in such a way that it counteracts the change in pressure, tending therefore to maintain a uniform pressure in the furnace chamber for all rates of combustion. In this way the excess suction of the chimney, beyond that required to remove the gases from the boiler, is eliminated, and the chimney has but one function to perform, that of removing the gases of combustion from the boiler fires instead of having also to supply air to the furnaces. As the entire supply of air is controlled by the power-driven blower, which is independent of atmospheric conditions, the fire temperature may be controlled closely with great rapidity.

In analyzing the effect of balanced draft, in raising the efficiency and capacity of boilers, it is necessary to consider the matter from several points of view. About 12 pounds of air are required per pound of carbon burned to complete combustion, and since any air in excess of this amount does not combine with the coal in combustion, but merely dilutes and cools the gases, it can be seen that only when the correct amount of air is obtained does the fire develop its maximum temperature.

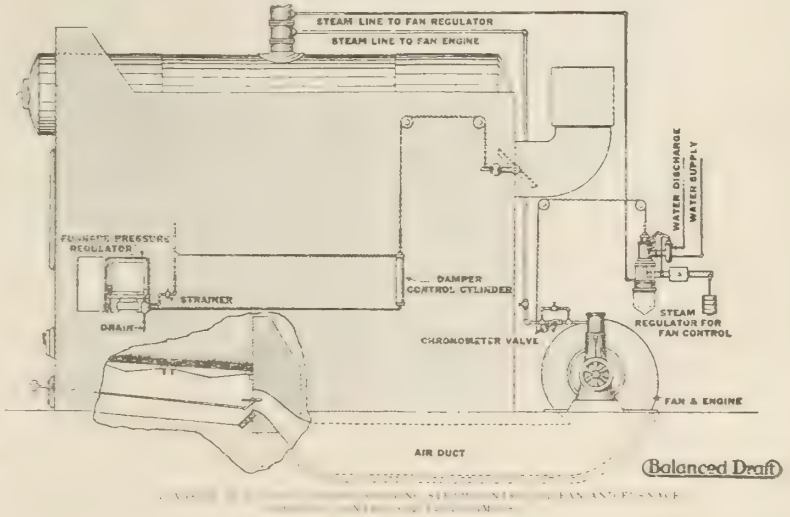

FIG. 4.

As a boiler absorbs heat in proportion to the difference of temperature between furnace gases and itself, the higher the temperature of the furnace gases above that of the boiler, the more rapid and greater, obviously, will be the absorption of heat by the latter. It is not only in this way that the thermal efficiency of the fuel is raised, however. By eliminating all excess air, the volume of gas for any definite weight of coal consumed is reduced to a mini-

mum, and it follows, therefore, that the velocity of these gases in passing from the furnace through the boiler and into the chimney is proportionally reduced. The time during which the gases are in contact with the boiler is an element which affects the heat transfer from gas to boiler, hence it naturally follows that the reduction in the velocity of these gases represents a direct gain in the heat absorbing capacity of the boilers, and is somewhat analagous to increasing the heating surface but without increasing the radiation and construction losses incident thereto.

The comparatively slow movement of gas made possible by the balanced draft is giving most gratifying results by enabling increased evaporation per pound of coal, permitting in many instances the use of a lower grade of coal than could be used otherwise, lower depreciation and lower maintenance charges, while the smaller coal consumption affects reduced labor costs.

TRIED TO SEND WORD TO BOSTON

Ontario Section of A. S. M. E. Observed the Fortieth Anniversary of Society's Inception

The fortieth anniversary of the founding of the American Society of Mechanical Engineers was celebrated by the Ontario section of the society at a meeting in the School of Science building, Toronto, on Nov. 5th. Telegrams were received and read from the parent society in New York and from a number of local sections in the United States, and other engineering bodies expressing the cordial feeling between engineers and congratulations on the fortieth birthday. There was also received a cablegram from the Institution of Mechanical Engineers of London, England, reading:

"Heartiest greeting on occasion fortieth anniversary. Events recent years, which demonstrated importance of engineers to civilization and established their power in industrial world, indicate necessity for continued expansion of engineering societies' activities, signed Institution of Mechanical Engineers of London."

Prof. James Trail gave an illustrated talk on the Power Canal of the Chippawa development of the Hydro Electric Power Commission. This was specially arranged as advance information for the members, who have been invited by the Commission's engineers to visit the canal. This trip to Niagara will take place within a few weeks and further announcement will be made.

After the lecture, an attempt was made to get in touch by wireless telephone with the Boston Section of the A. S. M. E., who were expected to be sending out messages in connection with their part of the anniversary celebration. The local receiving apparatus under the care of Messrs. Rosebrugh, Duncan and Hill, of the Faculty of Applied Science of the University, was working perfectly and picked up messages from a number of sources but none from Boston. The audience listened through multiple telephone receivers to a concert received over the wireless telephone and were much interested in a description of war time wireless by Mr. Duncan. As the expected Boston message later came by ordinary wire it would appear that the local electrical engineers had done their full duty.

CHEAP POWER FOR ALBERTA IS URGED

Public opinion in Alberta appreciates the fact that the production and distribution of cheap electrical energy is of cardinal importance to the general progress and prosperity of the province. At a recent meeting of the Alberta Associated Boards of Trade the following resolution was passed:

"That in view of the beneficial results in other provinces, we urge on the Provincial Government the extreme importance of the development of cheap power in Alberta, whether from water-power, coal, natural gas, or other source, at the earliest practicable moment."

The urgent necessity of providing for a comprehensive system and policy of power production and distribution in the Prairie Provinces has on a number of occasions been pointed out by the Commission of Conservation. Mr. James White, deputy head of the commission, in a paper read at the Calgary Industrial Congress last year, indicated that the proper future solution of Alberta power problems lies in electric generation from coal in comparatively large super-power central stations properly located both with regard to coal mines and power distribution centres and using small coal that would otherwise be wasted. The paper reviews the various other possible sources as follows:

"Owing to the unique characteristics, its special adaptability for various purposes, and the possibility of its rapid exhaustion, natural gas should be zealously conserved for use in its sphere of greatest efficiency. In my judgment, this sphere is not in the development of power on a wholesale scale.

"The water-powers of Alberta, valuable though they be, are, nevertheless, limited both with respect to magnitude and situation. Owing to low-water conditions, water power must be augmented by power from others sources.

"Now the great source to which Alberta must look for power is her coal. During recent years, the great advance made in the art of the production of steam power is phenomenal. This advancement has given coal, as a prime agency for power development in competition with other prime agencies, almost a premier position. Those interested in the furnishing of power on a wholesale scale in Alberta must make their research into, and selection from, the achievements made in recent years in the field of power produced from coal."

In connection with this move for public or co-operative efforts towards well organized power production and distribution, it is of interest to note a recent statement by Mr. H. G. Acres of the Ontario Hydro-Electric Power Commission:

"Under co-operative municipal ownership, a block of power delivered to the outgoing lines at Niagara is not valued by what it can profitably be sold for, at so many dollars per horse-power per annum, but by what it means to the individual citizen as an agency for increasing his comforts, conveniences and general standard of living, and for facilitating increased commodity production. Such conditions tend toward the building up of the greatest asset any country can possess, an increasingly prosperous and contented population."

WATERWORKS LOSSES

The great benefits derived from a water waste survey cannot be too strongly stated. In almost every waterworks system which has not been tested in this way, large leaks or other wastes are certain to exist.

Even the most efficient systems, when tested by pitometer surveys, almost invariably reveal poor, but easily remedied conditions at one or more points. These conditions, if allowed to remain, usually involve an unknown, but very expensive, drain on the operating expenses or a loss in revenue.

A recent example, typical of conditions revealed by such a survey, is that of the waterworks system of a city in the state of Indiana, which supplies a population of some 75,000. In this case, the survey exposed conditions which when corrected reduced a daily consumption of some 10,000,000 gallons by an average of 669,000 gallons. The underground leakage amounted to over 500,000 gallons per day which, at 5 cents per thousand gallons, represented a waste of over $9,000 per annum. Many other defects were brought to light, including the service to a large packing plant supplied on meter rate; a supposedly disused 4-inch service had never been shut off and unmetered water was being supplied through it. The meter on the other supply pipe for this packing plant, due to a wrong set of gears on the dial, was registering 45 per cent slow. The annual loss to the department in this case alone was estimated to be over $3,000. In another portion of the system, where the piping was old, the night consumption was out of all proportion to the day rate. Investigation exposed a 1-inch connection discharging full into an abandoned vault and three 1-inch services broken off at the mains. Approximately 35,000 gallons were wasted daily in a public school where the fixtures were running continuously night and day.—L. G. Denis.

Increasing Conduction and Decreasing Fuel Costs

The Effects of Scaly Deposits on the Water Side and Sooty Deposits on theFire Side of Heating Surfaces in Fire Tube and Water Tube Boilers.

By WM. R. VAN NORTWICK

DUE to its scarcity and high price the problem of fuel conservation is to-day receiving more attention than at any time in the past. Great thought has been given to the development of the modern stoker so as to get every heat unit out of the fuel and into the furnace. Thousands of dollars have been spent by the boiler manufacturers in order to take the heat units from the furnace and turn them into increased steaming capacity. One of the well-known boiler companies recently spent over a year experimenting and testing in order to ascertain the most efficient type and arrangement of the baffles.

Makers of prime movers, generators and motors retain expensive designing and testing departments to add a fraction of a per cent. to the efficiency of their products. While all this expense and refinement in design naturally is more than returned in the form of reduced fuel consumption, a great many plants are wasting materially larger amounts through lack of attention to the continually decreasing conductivity of the boiler.

The ideal design of a steam generator would be one in which the fire would come in direct contact with the water—with no wall of metal between. Of course this is impossible and we are compelled to interpose the wall of metal between the fire and the water. Great pains have been taken to reduce this wall to its smallest possible thickness with a maximum conductivity.

However, the very operation of the boiler tends to decrease the ability of the boiler to transmit the heat units from the fire to the water with a constant decrease in efficiency and increase in fuel consumption to accomplish a given result. This is due to the soot deposited on the tubes from the fire and the scale deposited from the water.

The fuel in burning produces a fine soot or ash which, carried by the draft, finds lodgment on the top of the tubes of a water tube boiler or in the flues of a fire tube boiler. It is strange that progressive engineers failed for so many years to realize that this soot (which is one of the best heat insulators known) retarded, more or less effectually, the transference of heat to the water. It is only of comparatively late years that any mechanism has been developed for mechanically blowing this soot from the tubes. Even after equipment of this character was developed it was extremely hard to interest the otherwise progressive consulting and large operating engineers. The sales engineers who were pioneers in the introduction of this type of equipment in New York city found it almost impossible to make any headway in its exploitation. In fact the speaker was, through his acquaintance with the consulting engineers on the job, largely responsible for the first installation secured in New York city. I mention this to indicate to you how recently this subject received real engineering consideration.

It is true that the steam lance has been used in plants for some time, but this was principally used to partially blow the soot from the tubes when it had accumulated to such quantities as to interfere with the draft and tended to slow down the fire. The fact that there is only one insulator more efficient than soot had apparently escaped notice and the soot was allowed to remain on the tubes in sufficient quantities to cause a considerable fuel loss. To-day the use of the mechanical soot blower is becoming more common, although there are many boilers to-day which are not so equipped.

The soot, which is referred to, is not necessarily unconsumed carbon, but is more often ash. It resembles but little our common conception of soot in that it is more often white, red, brown, gray, or green than black. The soot often fuses at fairly low temperatures, with the result that the tubes being insulated cannot absorb the heat and the chimney temperature rises. The higher temperature causes the soot to fuse, thus further insulating the tubes and raising the temperature.

The possible loss due to soot is indicated by a recent test run at the plant of one of the largest electric light plants in the country. Figures from a new and perfectly clean horizontal water-tube boiler of 600 h.p. capacity showed the uptake temperatures to average 550 degrees on the first day and 650 degrees on the fifth. This increase of 100 degrees in only four days indicates an increased fuel consumption of about 5 per cent., due to failure to blow the soot from the tubes. Service tests have indicated that boilers blown every six hours show an increased efficiency of 4 to 5 per cent. over those blown every 24 hours.

"Tests made by Mr. A. W. Conklin, combustion engineer, showed the following temperatures:

	Near bottom 1st pass	Top 1st pass	Bottom 2nd pass	Top 3rd pass
Hand blown	1697	954	727	618
Cleaned by steam blower	1691	934	649	527

"as temperatures were read at the points indicated in a horizontal water-tube boiler. In the first case the tube surface was blown thoroughly by a steam lance and the average temperature of the flue gas was 618 degrees. In the second case with the steam blower in use the exit temperature was 527 degrees, the difference in temperatures representing between 4 and 5 per cent. gain."

The removal of soot by mechanical methods is a comparatively simple task provided a properly designed and installed soot blower is obtained. However the elimination of water scale in the same boiler is a much more complicated problem. This is due to the character of the substance as well as the location in the boiler in which it forms. This water scale is not only an excellent heat insulator but is the cause of numerous more or less serious boiler failures. One of the large boiler insurance companies in New York reports that the large majority of their claims arise from burnt tubes due to scale incrustations.

These scale incrustations are due to the presence, in the feed water, of foreign material carried either in suspension (as clay and fine vegetable or organic matter) or in solution—as the carbonates, sulphates and chlorides of the various earth salts. The most common mineral substances so found are the carbonates and sulphates of calcium and magnesium, although the chlorides of these salts are often present in lesser quantities.

This scale thrown out of suspension or solution in the boiler appears in three forms: (1) scum; (2) mud, and (3) solid scale. The scum, which floats on the surface of the water, may, when first formed, be removed by means of the surface blow-off. If allowed to accumulate it will finally sink and attach itself to the tubes or shell in the form of mud or scale. The mud is soft, very often in an almost liquid condition, and may be blown out through the blow-off. If allowed to remain in the boiler it may combine with the other scale-forming material to form hard scale or may be baked to the boiler surface. The scale occurs as a stone-like deposit ranging from a porous, chalk-like substance, which is brittle and easily broken, to a dense cement-like stone which is often hard to break with a hammer.

The carbonates will, if present in certain forms, be thrown out of solution by heating to a temperature slightly in excess of 212 degrees for a sufficient

period. This drives off the extra molecule of carbon dioxide, leaving a monocarbonate which is insoluble in water. This scale will be found usually in large quantities in the third pass of a water-tube boiler.

While fairly hard this form of scale is inclined to be more porous and softer than the sulphate scales which are deposited on the application of heat of much higher temperatures. This harder scale will be found in the first and second passes, particularly near the baffles where the tubes are subjected to the highest temperatures.

Where the scale-forming material is (like sodium chloride, or common table salt) incapable of being thrown out of solution by heating, it is often precipitated in crystalline form, due to concentration.

In addition, scale is often formed by the introduction into the boiler of oils or grease. This takes the form of lime soap, iron soap, etc. An indication of the amount of scale which may form, from these various causes, is found when it is realized that in a 100 h.p. boiler during one month's operation, 300 pounds of solid matter may be precipitated on the tubes from water containing only 7 grains per gallon, while with some spring waters 2,000 pounds may be deposited in the same period.

Many long and accurate tests have been made to determine the cost to the plant owner, as measured at the coal pile, due to the accumulation of scale in the boiler. No hard and fast rule can be laid down as to these losses, due to the fact that the character of the incrustations varies with the different feed waters.

Professor Schmidt, of the University of Illinois, from a series of tests with boiler tubes coated with scale of varying thicknesses up to ⅛ inch, draws the following conclusions: (1) Scale varying in thickness up to ⅛ inch causes a heat loss varying from insignificant amounts up to as much as 10 or 12 per cent. (2) The loss increases somewhat with the thickness of the scale. (3) The mechanical structure of the scale is of as much, or more, importance as the thiskness in producing this loss. (4) Chemical composition, except in so far as it affects the structure of the scale, has no direct influence on its heat-transmitting qualities.

An example of the varying effect which scale may have on the conductivity of the boiler tube may be noted from the following table showing results of sixteen tests made at the University of Illinois:

Influence of Scale on Heat Transmission

No.	Thickness of Scale inches	Character of Scale	Dec. in Conductivity due to scale Per cent.
1.....	trace	Hard, dense	9.1
2.....	.02	Hard	2.02
3.....	.033	Soft	4.3
4.....	.033	Very hard	3.5
5.....	.038	Medium	4.03
6.....	.04	Soft	6.82
7.....	.04	Hard, dense	3.07
8.....	.042	Very soft	9.54
9.....	.047	Hard	2.75
10.....	.065	Medium	2.39
11.....	.07	Soft	2.38
12.....	.07	Hard	4.43
13.....	.085	Soft	19.0
14.....	.089	Very soft	4.95
15.....	.11	Hard	16.73
16.....	.13	Hard, dense	6.75

While there is considerable range to the reduction of conductivity noted, any of the losses found, if reduced to the coal pile cost, would amply repay for the removal of the scale.

Tables have been prepared by various interested parties showing that 1-16 in. of scale will increase the fuel consumption 15 per cent; ¼ in., 60 per cent., etc. It will be seen from the foregoing remarks that this relation does not strictly hold. If the scale is hard and dense and practically waterproof, it will doubtless be an effective heat insulator, while if it is porous, as many scales are, the water will be able to permeate the scale, and, reaching the boiler metal, transmit the heat with comparatively small fuel loss.

One hundred and twenty tests made by the Illinois Central Railroad indicated an average increased efficiency, due to thoroughly cleaned tubes of 11 per cent., while E. M. Fiske states that as a result of tests made for three months, previous to and three months after scale was removed from a boiler, it was found that the result, at the coal pile, was 10 per cent. in favor of the clean heating surface.

It is needless to recite further instances of savings effected by thoroughly removing the scale incrustations from the tubes, to indicate the possible savings in any plant embodying steam boilers. However, it might be well to state that while the instances cited have dealt with water-tube boilers, equal or greater results may be shown in those of the fire, or return tube type. One instance which came to the speaker's attention may suffice as an illustration. A well-known varnish company, whose factory, in Newark, N.J., incorporates fire tube boilers, of a well-known make, were recently overhauling their entire plant.

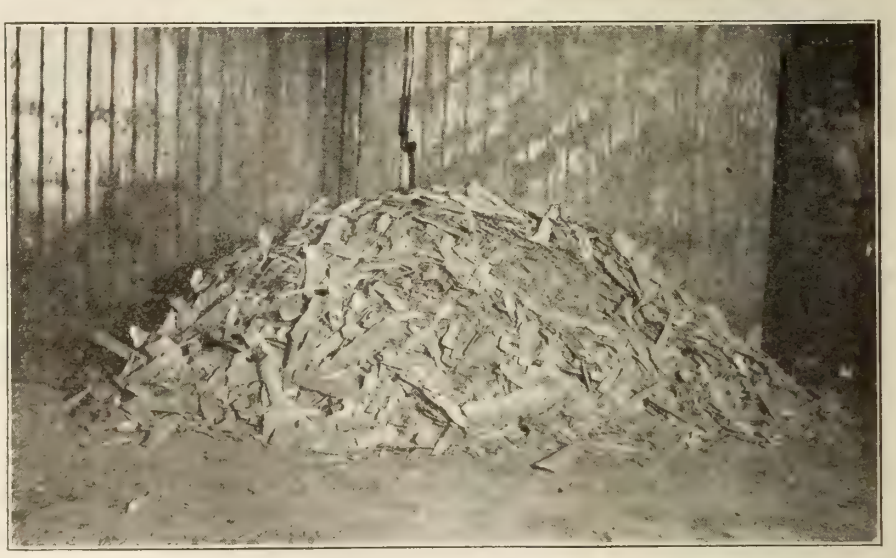
Although they doubted the necessity of doing so, they were persuaded to thoroughly clean the three boilers, removing the smoke scale or soot from the interior of the tubes and the water scale from the exterior. Previous to this cleaning they had been consuming daily, fuel to the value of $135. The boiler test, which followed the cleaning, showed a saving of 20 per cent. of this amount, or $27 per day.

Many additional similar instances might be recited, did this case need further proof. However, as previously indicated, aside from the fuel loss, there is a far more serious feature due to scale incrustations.

William Kent says in his "Steam Boiler Economy": "The effect of scale in a boiler ordinarily is to reduce both its steam generating capacity and its economy, since it is not a good conductor of heat and therefore diminishes the transmission of heat through the plates. It is also often highly dangerous whenever it accumulates to such an extent at a part of the shell which is exposed to the flame or to very hot gases that the plates become overheated and weakened."

In "Steam," published by the Babcock and Wilcox Company, we read:

"Not only has the presence of scale a direct bearing on the efficiency and capacity to be obtained from a boiler but its absence is an assurance against the burning of tubes.



SCALE REMOVED FROM THREE FIRE TUBE BOILERS

"Any formation of scale on the interior surface of a boiler keeps the water from such surface and increases its tendency to burn. Particles of loose scale that may become detached will lodge at certain points in the tubes and localize this tendency at such points.

"It has been proved beyond a doubt that a very large percentage of tube

losses is due directly to the presence of scale which, in many instances, has been so thin as to be considered of no moment, and the importance of maintaining the boiler heating surface in a clean condition cannot be emphasized too strongly."

The Hartford Steam-boiler Inspection and Insurance Company reports, as the results of one year's inspection, 157,804 boiler defects due to 22 causes. Of these, those due to deposits of scale or sediment numbered 41,026 or approximately 26%.

Could these scale incrustations be eliminated from the fuel burning plants of the country the saving effected in the national coal pile would be of staggering proportions and one of the direct results would be an appreciable price reduction to the consumer. Inasmuch as it is readily possible to secure this saving the apparent indifference of many engineers to this important matter assumes an aspect of almost criminal negligence.

One of the large central stations within a short distance of the heart of New York City was for some months ordering tubes in large quantities. During the war there was a great scarcity of material of this type and it was suggested that the speaker see them in regard to the advisability of thoroughly cleaning their boilers. They were readily responsive and after removing the scale incrustations from the tubes it was found that further tube renewals were unnecessary. In addition they also found that they no longer required the additional boiler capacity which they had contemplated installing.

The ideal feed water would, of course, be one which was neither acid or alkaline and which contained no traces of the earth salts. However, those waters which do not contain scale forming material invariably carry material which will pit or corrode the tube. While it is not the intention of this paper to enter into an extended discussion of corrosion and pitting of the boiler metal it is worthy of note that this action is far more serious than is the accumulation of scale. It cannot be easily detected and if not taken in time ultimately leads to ruptures in the boiler.

It might be well to note in passing however that the usual cure for this type of boiler trouble is to add some scale forming material to the feed water—such as carbonate of soda.

While there are no theoretically perfect feed waters, various treatments have been developed with the idea of purifying the feed water so as to eliminate the scale incrustations. Let us examine these very briefly.

Filtration. — Those materials which are in suspension, may often be filtered out by use of properly designed filters of sufficient capacity. Such material of this character as passes into the boiler may to a great extent be removed by the surface blow-off.

External Heat Treatment.—Where the principal scale-forming material is the bicarbonate of lime, magnesium or iron, beneficial results may be obtained by means of the application of heat to a temperature above 220° for periods of sufficient length to drive off the one particle of carbon dioxide, leaving a mono-carbonate which is insoluble in water and which is therefore precipitated and removed from the feed water.

Most waters, however, contain material other than the carbonates so that this treatment, which is expensive to install and maintain, only partially removes the trouble, allowing the harder sulphates to be introduced into the boiler.

Some waters carry salts which will not react to heat or other treatment and require to be evaporated and condensed. Even in cases of this kind sulphate of lime may make its presence known in the boiler. As shown in marine experience evaporation of sea water leaves scale-forming material in the water.

External Chemical Treatment.—This treatment, being only partially effective, is subject to the same criticism as the heat treatment. It allows scale to be formed in the boiler and the high cost of installation, interest on this cost and the cost of maintenance is practically wasted.

Combined External Heat and Chemical Treatment.—This system of feed water treatment is the best system as yet developed for external treatment. If anything it may be criticized for being too efficient. In plants in which it has been installed it has been found necessary to introduce scale-making material into the treated feed water to stop the pitting of the tubes. However, the principal objection to this system is that its cost is prohibitive. For the average plant the cost of such an installation would at least equal the cost of the boilers while the interest and maintenance costs could not be expected to be any lower.

Internal Chemical Treatment. — For many years the American power plant engineer has been buried under literature advocating the use of various "Boiler Compounds." The makers of practically all of them guarantee their product to successfully remove old scale and prevent the formation of new, regardless of local conditions. However, authorities are agreed that boiler compounds are not successful and should not be used. Mr. Albert A. Cary, the eminent consulting engineer, says "Never use any compound unless you know positively just what it is composed of, and how it will affect the impurities in your boiler and the boiler itself. In the treatment of boiler-waters, always start with a careful analysis of the water, made by a competent chemist who has experience in this line. Next, if you are thinking of using any chemical that has been offered for treatment of your boiler water, let your chemist analyze it. If you are dealing with straightforward people, they will generally tell you the exact composition of their material, which your chemist can verify easily, after which he will be prepared to advise properly."—(Engineering Magazine, June, 1897.)

Again in The American Machinist of December 7, 1899, Mr. Cary says: "The treatment of feed-waters inside of the boiler has been a practice of many years' standing, but in the light of recent progress is not to be commended. A boiler certainly has all that it can be reasonably expected to do when it is generating steam without being called upon to perform the functions of a chemical laboratory."

Even where the boiler compound is successful, or practically so, it is subject to criticism. Mr. William Kent says in his Steam Boiler Economy: "A thin scale may form on the tubes, be detached by the action of some 'boiler compound' and may then be carried by the circulation and deposited in a thick mass on the shell over the fire. This may cause a 'bagged' plate, or a crack and an explosion."

It is hard to tell just where to look for misrepresentation in the sale of boiler compounds so that it behooves the owner and engineer to be doubly on their guard in dealing with this type of material. One maker of a "boiler metal treatment" advertises that it is not a boiler compound and guarantees the claims made for the preparation, as presented in such high class power plant papers as "Power," "Combustion" and "Power Plant Engineering."

The U.S. Government made a test of this preparation and found after extensive experimentation that not a single claim was actually met and that the preparation was really injurious as pitting increased.

Despite the fact that the results of this test were printed and distributed, the company still continues to advertise the "Guarantee" of its claims.

One of the most rational criticisms made against the addition of chemical reagents to the feed-water may be found in the discussion by Mr. M. F. Newman on a paper entitled "A Novel Method of Handling Boilers to Prevent Corrosion and Scale" as read by Mr. Allen H. Babcock before the Annual Meeting of the American Society of Mechanical Engineers, December, 1915.

He says, in part: "While the method described by the author may be considered novel, it is by no means rational, since to impurities already present in the boiler feed there is being added more impurities, so that the final effect is to increase the impurities in the water in the boiler without any compensation in the way of removing or freeing the water from suspended matter.

"The application of precipitants to water within the boiler is irrational and at the best is a mere makeshift. In the process of generating steam nothing but pure water is evaporated so that there is a constant building up of impurities in

the water remaining in the boiler. This applies to soluble salt as well as the suspending matter.

"When the reactions for the precipitation of lime and magnesia are carried on within the boiler the result is to befoul the water with suspended matter and increase its density with soluble salts, so that more fuel is required for the generation of steam and a more frequent changing of the water to eliminate the soluble solids, as well as the suspended matter collected."

This required frequency of blowing down becomes very expensive and in time may exceed the savings expected from the treatment of the feed water.

Mechanical Scale Removal from the Boiler.—This then brings us down to the removal of the accumulated scale by mechanical methods. There is every reason to believe that the large power plants and central stations have adopted the most modern and economical practice in this portion of their boiler room procedure. These people have staffs whose duty it is to develop the plant efficiency to its highest point.

It has been the speaker's experience that every one of these large central stations is using mechanical methods of scale removal. The advocates of internal chemical treatment argue that by allowing the scale to accumulate the efficiency of the boiler is gradually dropping until the boiler is again cleaned. Engineers of experience believe this method of handling is far more economical than to concentrate the feed water by the addition of impurities to those impurities already in the water.

The engineers of the Babcock & Wilcox Company have made extensive and intensive study on the subject under discussion. Their conclusions are partially outlined in the following quotation from "Steam":

"It is necessary that in each individual plant there be a basis on which to judge the cleanliness of a boiler. It is, of course, impossible to keep boilers absolutely free from scale at all times, but experience in each individual plant determines the limit to which scale can be allowed to form before tube difficulties will begin or a perceptible falling off in efficiency will take place. With such a limit of scale formation fixed, the operatives should be impressed with the danger of allowing it to be exceeded."

It will be readily appreciated from the foregoing that the dense hard scale will form the most rapidly in that portion of the tube surface which is subjected to the highest temperature of the gases. This portion of the boiler is naturally found in the lower four or five rows of tubes in the first pass.

The practice of the large central stations consists of the frequent cleaning of these bottom rows together with three or four of the upper rows at each time. In this way the entire boiler is cleaned at least twice a year while the lower rows are cleaned every thirty to sixty days.

It but remains to bring to your attention a few requisities in connection with mechanical cleaners. The cleaner should be so designed and constructed as to thoroughly remove all the scale, in the shortest possible time, at the lowest cost to operate and should require a minimum of expense to maintain and repair, working with absolute safety to the boiler and operator.

Without reviewing the history of tube development to the present high standard, I would call to your attention that three methods of driving mechanical cleaners present themselves, i.e., air, steam and water. Where the plant is equipped with compressed air in sufficient quantities and pressure, the air driven cleaner is preferable. Failing in this steam may be used. The majority of plants have water at sufficient pressure, either from the feed or fire pumps,

TYPE OF CLEANER

to enable them to operate a water driven machine if compressed air is not installed and the plant conditions prohibit the use of steam.

A description of machines which will meet the requirements outlined above may not be out of place. The cleaners in question were designed by Mr. P. J. Darlington, a pioneer in the development of the air driven machine, although not now connected with the trade.

The action of the cleaner depends on the cutters being thrown out against the scale by centrifugal force. Inasmuch as centrifugal force depends directly on rotative speed the interior of the machine is designed for high speed over long periods. An examination will reveal a single steel blade, at all times subjected to the pressure medium. This blade is fitted to an eccentric cylinder bore which is necessarily out of round. The relation of the metals in blade and cylinder are as dictated by good engineering practice. A small portion of the blade's rotation utilizes the expansion of pressure medium.

Straight edged ports are provided for admission and exhaust, giving clean, quick action. The bearings are full, generous and placed far apart, insuring ease of running, smoothness of action and long life. At the air inlet end where it is hard to supply lubrication a roller bearing is furnished. The body of the motor is of bronze, giving lightness, while hardened steel wearing rings are provided where the motor slides against the tubes. This motor is furnished in two different strengths—one twice that of the other and may be driven by steam pressure as well as air.

The water driven motor has its bearings in one long inner shell, held always in line and away from the great mass of water operating the machine. The nozzle plate located at the extreme outlet end of the motor directs the water to a turbine wheel which, being shrouded, compells each drop of water to deliver all the work stored up in it before it is discharged into the boiler tube. No back pressure being present, the maximum efficiency is obtained. The body is of light bronze construction with steel wearing rings.

The parts of both types of motor are designed and constructed, having the purpose in mind for which they are intended. The bodies of the motors are made as large as possible and still permit the cleaner to pass through the tube. In fact so large are they that they act as tube gauges and the passage of the cleaner through the boiler tube is an assurance that it is clean.

With both air and water driven cleaners a swing frame head is furnished, so designed that three sets of cutters are thrown out against the scale. The arrangement is such that these cutters make contact with the scale and tube along a straight line. The cutters are so designed as to eliminate sharp points scratching or damaging the tube. Other cutting heads are furnished to meet peculiar scale conditions, each so designed as to properly do its work without damaging the tube.

Having secured efficiency through design and great rotative speed we find that this same speed and design enables the cleaner to quickly do its work—reducing waste boiler time and labor costs in cleaning.

In addition this excess speed and power, removing the scale quickly, allows the cleaner to advance rapidly, eliminating the necessity of the cutters laboring for long periods in one spot, cutting scale at the bottom of the tube and working against the uncovered tube at the top. This feature in addition to the design of the cutting head with its parallel action insures freedom from tube damage. This is particularly desired in cleaning fuel economizers incorporating cast iron tubes.

It but remains in closing to state that the conditions outlined as pertaining to boilers likewise hold for fuel economizers, condensers, evaporators and other tubular and pan mechanisms used in the power plant and chemical industry. Mechanical cleaners properly designed may be obtained for each size and type of mechanism which it is desired to clean.

The Theory and Practice of Electricity

In These Articles the Theory Will be Developed Sufficiently to Enable the Practical Man to Grasp the Underlying Principles of Apparatus Under His Care, Both Direct Current and Alternating

W. F. SUTHERLAND

D. C. Generators

IF one examines the field windings of direct current generators or motors, three different types will be observed, the field may be wound with comparatively coarse wire of few turns, with a large number of turns of fine wire or a combination of both may be employed. These three windings are different in character and produce different characteristics in the operation of the machine to which they belong.

Fig. 1 illustrates what is known as the shunt winding. It will be seen that it consists of a large number of turns of fine wire, the free ends of which are attached to the brushes of the machine. The external leads leading away from the machine, whether dynamo or motor, are also attached to these same brushes. The full voltage of the machine, if a generator, is available for sending current through the field coils. If we consider the case of the shunt wound generator first, as in all dynamo-electric machinery the generation of current is first started by the action of a certain amount of residual magnetism, present in the field magnets no matter how soft the iron. This generates an extremely weak voltage which, however small, causes current to flow through the field coils and thus creates a magnetic flux which in turn increases the generated voltage. The action is cumulative and the voltage rapidly builds up to a value fixed by the characteristics of the machine. It should be noted that a shunt wound generator should always be started up under no load, that is with the

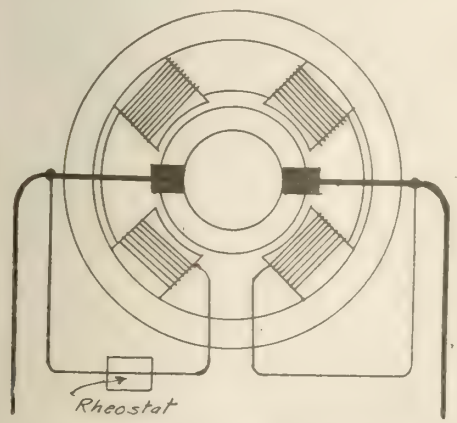


FIG. 1—SHUNT WOUND GENERATOR

exterior circuit to motors, lamps, etc., disconnected or open, for if it were closed the initially weak voltage generated would cause current to flow through the load as well as through the field and so doing would delay the building up of voltage or prevent it altogether. In the shunt dynamo field circuit is usually placed an adjustable resistance or rheostat for varying the voltage of the generator. Assuming the speed to be constant if more resistance is cut into this circuit the current through the field coils is lessened and the magnetic flux decreased in consequence. Since armature conductors are rotating at the same speed they will not be cutting as many lines of force and in consequence the voltage of the machine will automatically fall off. On the other hand if the rheostat be cut out the field current will be increased, more flux will

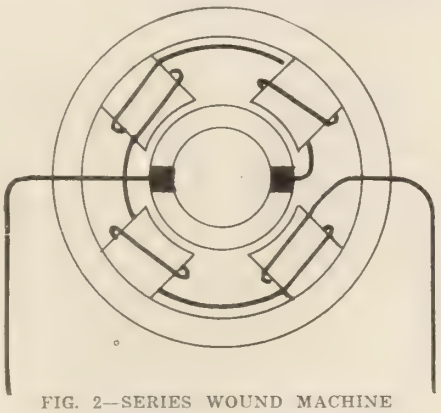

FIG. 2—SERIES WOUND MACHINE

pass across the air gap and in consequence the voltage will be raised.

Fig. 2. shows how the voltage varies with increased load on a shunt generator. The load is represented on the horizontal line at the bottom, while the voltage generated is shown to the left. With increasing load the voltage drops slightly for the first part of the curve as shown. For instance, at no load, the terminal voltage of the machine chosen will be about 120 volts and at a 25 ampere load it will have fallen about 2½ volts. At 30 amperes it will only be about 115 volts, while at 52.5 amperes, a voltmeter across the line would only register about 100 volts. From this point on in this particular instance the voltage drops off with increasing rapidity until when the machine is short-circuited only about twelve volts will flow.

The reason for this voltage drop is seen in the comparative resistance of the field circuit to that of the exterior or load circuit. At no load the field circuit is the only path through which the current generated can flow and full voltage is available for this purpose. As a load is applied the resistance of the load circuit falls off and that of the fields remains stationary. More and more current flows through the exterior circuit and less through the fields until with a dead short across the brushes the field coils carry no current whatever and thus generate no magnetic flux. The small current flowing at this period will only be that due to the residual magnetism inherent in the iron of the fields. This feature of the shunt-wound machine fits it for certain uses since it can never be overloaded to any great extent. Shunt-wound machines find considerable use in storage battery charging, being the only suitable form for the purpose. In ordinary practice the voltage generated is controlled by a field rheostat and a fairly constant voltage over a considerable load range can thus be maintained.

The Series Generator

As will be seen from Fig. 3, the series machine has a few turns of comparatively heavy wire in place of the many turns of fine wire on the shunt machine. Two machines of similar design and of the same size, one shunt-wound and the other of the series type, will require the same number of ampere turns for field excitation. In the series type the product of the whole generator current flowing through the fields by the number of turns equals the smaller current of the shunt type multiplied by the larger number of turns. The series wound generator cannot build up voltage unless it is connected to an external load since there would be no current flowing through the fields and any voltage generated would be due to residual magnetism only. Consequently the no load voltage of the series machine is zero as compared to the shunt-wound machine whose voltage under similar conditions is at its greatest value.

It may be remarked that the series wound generator is very seldom met with in practice, although the series motor is an extremely useful type and one used very largely where large starting torque and variable speed are required.

The Compound Wound or Motor Machine

The compound wound generator or motor combines the characteristics of both shunt and series machines. It has a shunt winding composed of many turns of comparatively fine wire and a series winding of fewer turns but heavier wire. The compound-wound generator has both a shunt and a series field winding. As the current supplied by the generator to the external circuit increases, the current through the series field is also strengthened and this in turn causes an increase in the magnetic flux generated by the series wind-

ing. While this is occurring the shunt winding is taking less current as the load increases, just as in the shunt-wound generator and by proper proportioning the increasing strength of the series winding can be made to balance the decrease in the shunt and so maintain the magnetic flux constant. It is thus possible to maintain a constant voltage irrespective of the load imposed, as shown by the line a, b, in Fig. 2.

The series winding can be made relatively stronger than the shunt and when this is done the machine is said to be over-compounded. The magnetic flux in this type of generator will increase with increasing load and the voltage in consequence will rise. This characteristic

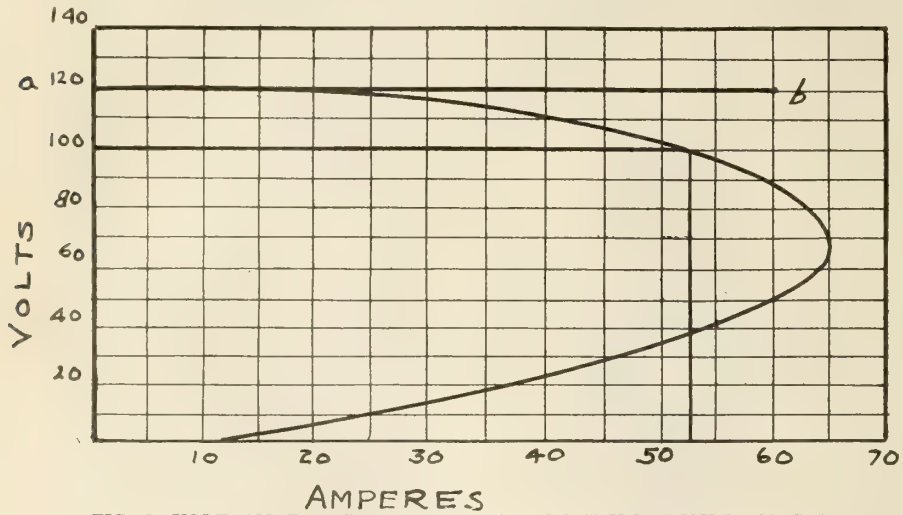

FIG. 2—VOLT AMPERE CHARACTERISTICS OF SHUNT WOUND MACHINE

is of use in the case of a d. c. generator feeding a transmission line, since it takes care of increased line-drop with increasing load and thus maintains the voltage constant at the receiving end.

If the series field is relatively weak the voltage will drop with increasing load and the machine is said to be under-compounded. It is possible to regulate the compounding effect of a generator by means of a resistance shunted across the series fields and by thus passing a certain amount of current weaken the series field.

It is also possible to have the series and shunt windings oppose each other. In this case the term differentially compounded is used, while if in a generator or motor the two windings assist each other, the term cumulative compounded is given.

D. C. Motors

It is a well known fact that a d. c. generator operates equally as well as a motor and it is sometimes of use to know what changes would be necessary if it be desired to make this change. The direction in which a direct current generator will operate if run as a motor can be quite easily determined.

It is well to remember that in the dynamo the armature conductors are pushed by the mechanical force applied from outside in a direction opposite to that in which they would go in a motor if the current in each case had the same direction. With this in mind, then, if the direction of the armature current and the direction of the magnetic flux through the machine both remain unchanged or if both are changed when the machine is changed from a generator to a motor, the direction of rotation will be reversed.

If either one of the above directions be changed, and the other remain the same, the direction of rotation will remain the same.

To reverse the direction of rotation of a motor either the direction of the armature current or of the magnetic flux must be changed, but not both.

If a shunt generator be changed to a motor it will run in the same direction as before, no matter which way the current enters or leaves it, for, if the polarity remain the same, the direction of the magnetic flux, due to the shunt

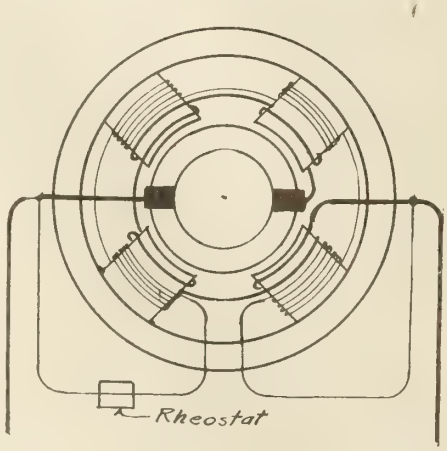

FIG. 4—COMPOUND WOUND GENERATOR

field will remain as before, while the direction of the armature current will be reversed and if the polarity be changed the magnetic flux will reverse in direction, while the armature current will remain unchanged.

This leads to the general statement that a shunt generator when changed to a motor will operate in the same direction regardless of the polarity of its terminals, if no change in connections has been made.

If a series generator be changed to a motor it will reverse in direction, for if the polarity is kept the same both armature and field currents will be reversed and if the polarity is reversed the armature and field currents will both remain as they were.

The compound wound generator presents a slightly more difficult problem when changed over into a motor, for it will combine the characteristics of both shunt and series motors and if a cumulative compound wound generator will become a differentially wound motor, and if it were a differentially wound generator it will become a cumulative compounded motor.

If a motor be connected up differentially it will present a curious phenomenon. It may start up under the influence of the series winding, and after the shunt field current has had time to build up in value the armature may stop and start to rotate in the opposite direction.

AIR BOOSTER FOR CENTRIFUGAL PUMPS

Two single-stage centrifugal pumps were sufficient to keep down the water at the Algoma mine, Ironton, Minn., when the flow increased owing to the cessation of pumping at an adjoining property, says H. H. Hunner in Engineering and Mining Journal. One pump was driven by a 75-h.p. motor at 1750 r.p.m., rated at 1290 gal. per min. against a 165-ft. head, and was pumping at approximately this head. The second pump was direct-connected to a 100-h.p. motor making 1750 r.p.m., and was rated at 1500 gal. per min., with a 170-ft. head. Suction and discharge for both pumps were 6-in. diameter pipes.

Elbows on the discharge pipes were tapped for 1-in. pipe connections about five feet from the pumps, connected to an air line, and the valves were slightly opened on a 90-ft. air pressure. The added pressure increased the capacity of the pumps by 200 or 300 gal., which was sufficient to take care of the increased flow of water. The small amount of air used was not noticeable on the air line.

HARDENING CONCRETE

Experiments by the United States Bureau of Standards to develop a method of accelerating the hardening of concrete, especially when it is to be used in wet or damp situations, have shown that 4 per cent. of calcium chloride added to the mixing water increases the strength of concrete at the age of one day 100 per cent. or more. In some cases in two days the strength equalled 75 per cent. or more of that normally attained in one month.

A Course of Instruction for the Graded Certificate

We Will in This Course Go Through the Mathematical and Theoretical Work to Cover Every Grade of Certificate Issued by the Ontario Board

By T. H. FENNER

HAVING discussed in previous articles the construction of the boiler, it will be in order to take up now the operating features of the furnace and boiler.

In an externally fired boiler, such as is generally used in stationary plants, the furnace is really a separate and distinct apparatus, apart from the boiler. The function of the furnace is to provide a proper receptacle for the efficient combustion of the fuel and the setting is to confine the products of this combustion to a certain path, in which is contained the boiler. The function of the boiler is to contain the fluid to be heated, and to transmit the heat from the products of combustion on the outside to the fluid on the inside. It is, therefore, quite evident that one may have a perfectly efficient furnace, and a very inefficient boiler, or on the other hand a very efficient border, with an inefficient furnace.

Boiler efficiency will depend on the external and internal condition of the boiler shell, tubes, and all heating surfaces. It will also depend to some extent on design, in so far as that affects the circulation of the water. That, however, is a condition entirely out of the reach of the operating engineer, whereas the condition of the heating surfaces is entirely under his control. The careful engineer will therefore see that the fire side of heating surfaces is kept free from deposits of carbon, or soot, and the water side free from deposits of scale, grease, etc. The following experiment, carried out by Professor Durston, will illustrate what a very little deposit of grease can do in reducing boiler efficiency. A piece of tube, 2½ inches diameter, and .135 inches thick, was used for the test, and was first tried when clean, and next with a thin coating of grease on the water side of the tube. The decrease in efficiency was 11%, an average of several experiments.

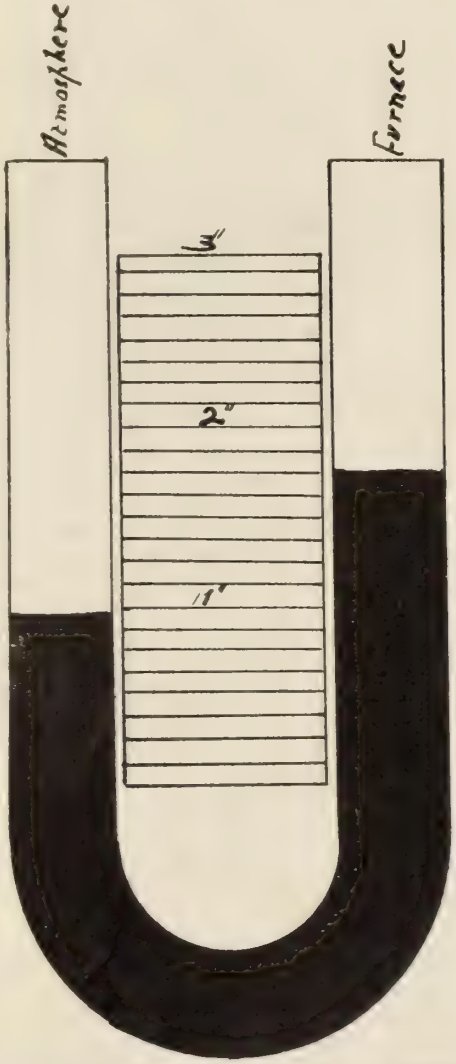
The accumulation of soot on the fire side of heating surfaces is also very bad, soot being one of the worst conductors of heat that can be found.

There is another evil connected with soot or sooty deposits on heating surfaces, which does not come into play while the boilers are operating, but is sometimes very active when they are shut down. There is often a certain amount of sulphur contained in this deposit, and when boilers are standing idle, and moisture is present, very favorable conditions for corrosion are present.

These conditions are, as we have said, entirely under the control of the man in charge, and he should watch them carefully, and keep them right.

Furnace Efficiency

Furnace efficiency depends on the construction and condition of the setting, type of grate bars, intensity of draft, and condition of the fuel bed. In the final analysis, the horsepower that can be developed by any boiler depends entirely on the number of pounds of coal that can be burned per square foot of fire grate per hour. This again depends on the physical condition of furnace and setting, and the quantity of air that can be delivered to the furnace.



DRAUGHT GAUGE SHOWING ¾-IN. WATER COLUMN

If natural draft is used, this will depend on the chimney. If forced or induced draft is used, the chimney then becomes merely an apparatus for delivering the gases, and not a means of creating draft. Whichever means are employed for securing the necessary air for combustion, the air should only be allowed to enter at points where it can be controlled. That is under the grate bars, and over the fire if necessary, through openings under the control of the attendant. Unfortunately, the whole boiler setting is susceptible to air leakage, and to keep it tight is a continuous fight on the part of the man in charge. Every opening where a pipe is brought through the setting is a potential leak, also the frames of cleaning doors, as well as the doors themselves. Unless the brickwork is covered with an airtight composition there is a certain amount of leakage, through the bricks themselves, which are porous. Every crevice where a connection can be made between the outside and inside of the setting is a menace to efficiency and should be guarded against. It is not difficult. A lighted candle passed around the setting wherever a leak is suspected will give sure indication of its presence, by the drawing in of the flame. This should be done very frequently, as little defects are constantly developing. There has been so much said on this subject that it seems almost a waste of time to mention it again, but the fact remains that many engineers do not even yet realize the importance of airtight settings. Every ounce of air which leaks through the brickwork of a furnace takes heat from the products of combustion, and carries that heat away up the stack. There is enough heat lost in that way which cannot be avoided, as we shall see later, without adding avoidable losses. Air leakage is then one great source of loss of efficiency. Over supply of air in the proper place is another, and under supply is still another. The first of these lowers the efficiency in the same way as air leaks do, while the latter affects efficiency through incomplete combustion. Perfect combustion can only be assured by the admission of the right quantity of air, and we will go into the methods of determining that quantity very carefully. Before doing so, however, we will obtain an understanding on the chimney and its relation to draft, that will help us in our consideration of the whole subject.

Meaning of Draft

Draft may be defined as the difference between the pressure of the atmosphere and that of the column of hot gases in the chimney. The force of this draft is usually expressed in inches of water,

and to make this clear we will show here what exactly is meant by 1 inch of water column.

The pressure of the atmosphere is 14.7 lbs. per square inch. This is sufficient to balance a column of water 33.8 feet in height. In other words, P or pressure is equal to the head of water multiplied by .434, or P=.434 H. Then

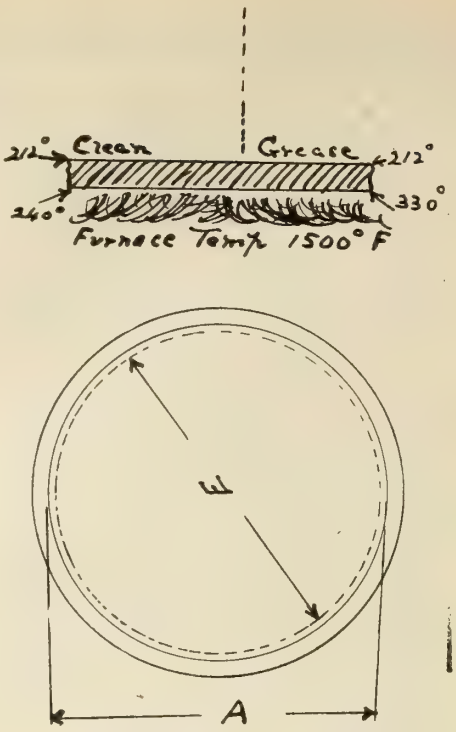
$$H=\frac{P}{.434} \text{ or } H=2.304 \text{ for 1 lb. pressure.}$$

That is a column of water 2.304 ft. high and 1 square inch in area is equal to 1 lb. per square inch pressure. Then 1 ounce per square inch will be equal to 2.304 ft. divided by 16. This is equal

$$\text{to } \frac{2.304\times 12}{16}=1.728 \text{ ins.}$$

Then 1.728 inches of water column is equal to 1 oz. pressure. Draft is usually expressed in inches of water because it is most convenient to measure in those units. There are numbers of draft gauges on the market which all have points of merit, but the ordinary U tube can be made in a few minutes by any engineer. All that is needed is a piece of gauge glass and a rubber tube. The glass is put in the flame of a gasoline torch and heated till it can be worked into shape by hand. A piece of rubber tubing is fitted over one end, and the loose end of this tube can be fitted over a pipe communicating with the space where the draft is to be measured. A length of a wooden rule is secured between the two legs of the U, and water is put in about half the height of the legs. As one end of the tube is free to the atmosphere, any difference of pressure is immediately shown by a difference of level in the water in the two legs, and the force of the draft in inches of water read directly from the rule.

The intensity of the draught is dependent on the difference between the density of the column inside the chimney and that outside the chimney and the height of the column. The density of the gases will depend upon their absolute temperature. Absolute temperature is found by adding 460 to the reading of the Fahrenheit thermometer or 273 to the reading of the Centigrade thermometer. As air is increased in temperature, it is increased in volume, and the column of gases in the chimney is very largely composed of air. There are, however, other gases present, such as carbon dioxide, carbon monoxide, and slight traces of other gases. These will make some slight variation to the specific heat of the gases in the chimney and therefore affect the volume at different temperatures. However, we do not have to go into this question as these matters have been dealt with by Rankine and others, who have given us the result of their labors. All we have to do is to apply the formulae they have given us. The following formula, deduced by Rankin, gives



TOP—EXPERIMENT ON PLATE.
BOTTOM—PLAN OF CHIMNEY

the force of the draught with a given height and density.

$$F=.192\ (D-d).$$

$$F=$$

Where F=force in inches of water. The factor .192 is used to convert pressure per square foot into inches of water. As density is reckoned in lbs. per cubic foot, the height or head would give pressure in lbs. per square foot. The factor .192 is obtained by dividing the pressure of 144 ozs. per square foot, which is equal to 9 lbs. per sq. foot, into the height of water column due to that pressure, 1.725 ins., or .192 ins. water column is equal to 1 lb. per square foot. The density of the hot gases varies with the absolute temperature, and can be found by dividing the absolute temperature at 32° by the absolute temperature of the hot gases, multiplied by .084. The density of the atmosphere is found by dividing the absolute temperature at 32° by the absolute temperature of the atmosphere, multiplied by .0807. Suppose we have a chimney 100 feet high and the outside air is 60, and the gases 600, we will have

$$F=.192\ h\ (D-d),$$

$$\text{Then } D=\frac{460+32}{460+60}\times .0807$$

$$\text{and } d=\frac{460+32}{460+600}\times .084$$

which works out to D=.076 and d=.038.

$$\text{Then } F=.192\ h\ (.076-.038)$$
$$=19.2\times .038.$$
$$=.72 \text{ inches.}$$

It must be remembered that these are purely theoretical formulae, and in practice results may vary considerably from them.

It has been found that the weight of gases discharged is a maximum when the absolute temperature of the hot gases, divided by the absolute temperature of the outside air, gives a quotient of 2 1-12. That is with the air at 60°, and gases at 622°, the result is

$$\frac{1081}{521}=2\ 1\text{-}12$$

This does not mean that the force of the draught or difference of pressure is greatest, but that the actual weight or quantity of gases is greatest.

The draught at the chimney base will always be higher than that over the fire, and it often occurs that when a large battery of boilers are attached to one stack, by a long breeching, the draught on the boiler furthest from the stack will be much less than on that nearest the stack. Restricted passages affect draught pressure in the same way that short bends and narrow openings in steam or water pipe affect steam or water pressure.

Calculations on heights of chimneys for any particular draught are apt to be considerably out, due to these conditions. Draught that may be adequate with a large size of anthracite will be useless with a small size of buckwheat.

Horsepower of Chimneys

The formula and table given here are from Kent's Hand Book, and may be accepted as good practice. In drawing up the table, a consumption of 5 lbs. coal per horsepower hour has been allowed, which is, of course, very high. The author, however has adopted that figure as a factor of safety to allow for worst conditions.

The area of the chimney is supposed to be diminished by a lining of gas which has no velocity. This is to allow for the friction of the ascending gases. The effective area of the chimney will therefore be the actual area less this 2 inches all round, and the formula for determining this is, if E=effective area.

$$E=A-.6\sqrt{A}$$

The horsepower varies directly as the area, and as the square root of the height. From this Professor Kent deduces the formula,

$$\text{H.P.}=3.33\ (A-.06\sqrt{A})\ \sqrt{H}$$

$$\text{and } E=.3\ \text{H.P.}\div\sqrt{H}$$

$$\text{and } H=\frac{.38.P}{F}$$

Suppose we have a plant of 2000 h.p. and the height of chimney is 175 feet, then the effective area will be

$$E=2000\times .3\div\sqrt{175}$$
$$=600\div 13.22$$
$$=45.38$$

Then actual area for square chimney would be

$\sqrt{E}+4$ inches=equivalent side

$6.73+.3=7.03$ feet side

$=49.43$ sq. ft. actual area

With H. R. T. boilers it is often the rule to take chimney area as 1-9 the grate area, irrespective of height. If we apply this to the last case, we may compare results.

$2000\times 15=30000$ sq. ft. heating surface

$3000\div 40=750$ sq. ft. grate surface

750÷9= 83.3 sq. ft. area of stack
With water-tube boilers
2000×10=20000 sq. ft. heating surface.
20000×40=500 sq. ft. grate.

Size of Chimneys for Steam-boilers.

Formula, H.P. = 3.33 $(A - 0.6\sqrt{A})\sqrt{H}$. (Assuming 1 H.P. = 5 lbs. of coal burned per hour.)

For pounds of coal burned per hour for any given size of chimney, multiply the figures in the table by 5

SIZE OF CHIMNEYS.

500÷9=55.5 sq. ft. chimney area.
This rule then gives ample areas.
In general, it is better to be on the large side in area, as the area can always be checked by the damper.

Authorities differ as to whether it is better to have the gases pass through the setting with a high or low velocity. One school says that the high velocity gases scrub the heating surfaces, preventing a film of stationary gases from settling and forming an insulator. The low velocity school claim that with high velocities the gases do not have time to give up their heat, but go out of the stack at high temperature.

Every engineer can determine the point of damper setting at which he gets best results, at different loads, and, by noting the reading of his draught gauge, get a very good guide for his fireman to work to. A couple of hours' experimenting with a draught gauge, adjusting the damper to various points, and observing effects, will do a world of good without the help of any other instrument at all.

SEMI-ROTARY WING PUMPS

Prior to the war the manufacture of these pumps was very largely in the hands of German firms, but since that time British firms have been giving more attention to the production of these articles with a considerable measure of success.

A further extension of this manufacture is indicated in the announcement recently made that the well-known firm of William Beardmore & Co., Ltd., Parkhead Forge Rolling Mills, and Steel Works, Glasgow, have taken up the manufacture of semi-rotary wing pumps and are now in a position to fulfil orders for these.

Messrs. Beardmore are manufacturing these pumps in two different classes, the one being of a cast iron body with solid bronze fitttings, and the other of brass throughout.

Spindles in all cases are of high quality steel, and screwed pipe flanges are fitted to all pumps.

The firm intends to manufacture this pump in 12 different sizes and draws special attention to the complete accessibility for repairs, which can be carried out by removing the cover without disturbing the existing pipe line. The pumps are double acting and easily worked, can be operated either by hand or power, and can be used for lifting or forcing water, oil, petrol, and liquids generally.

SCREWED FITTINGS

The writer noticed in the October 20th issue of Power House an article headed "Screwed Fittings" in answer to an inquiry, stating that there is no rule limiting size of which screwed fittings may be used on working steam pressure to 125 pounds.

Wish to advise this is an incorrect statement. As contractors, we are obliged to instal work of this nature to the approval of the Government Boiler Inspection Department, who demand that all fittings on steam lines over 15 pounds pressure have flanged fittings on all piping 2½ inches or over.

We trust that this statement will be corrected in your next issue.

Yours very truly,
GRINNELL COMPANY OF CANADA, Limited.
A. E. CLARK, Heating Engineer.

Editor's Note:—The answer was to a correspondent from Quebec, where there is no such law, as far as we know. In our answer we recommended the use of flanges in pipe over 2½ inches diameter, for convenience in installing and repairing.

MEETING OF THE W. A. M. E. E.

The Western Association of Mechanical and Electrical Engineers held their annual Grand Lodge convention in the city of Edmonton on the 4th, 5th and 6th of October last. A good time was spent, several important matters being discussed by the delegates present from various parts of the province. Among these important matters was the question of asking the Department of Education to organize through the Department of Technology instruction classes for stationary engineers, to be run on similar lines to the classes in mining instruction now run under the above department. It was the feeling of the engineers that the Steam Boilers branch of the Department of Public Works should draw out the syllabus of instruction for these classes in order that the instruction shall be of the greatest benefit to the engineers when writing for higher certificates. A committee waited on Mr. Ross, the Deputy Minister of Education, and Mr. Campbell, the director of technical education, with this request and were assured that the department was in every way favorable to the idea.

What is Supersaturated Steam?

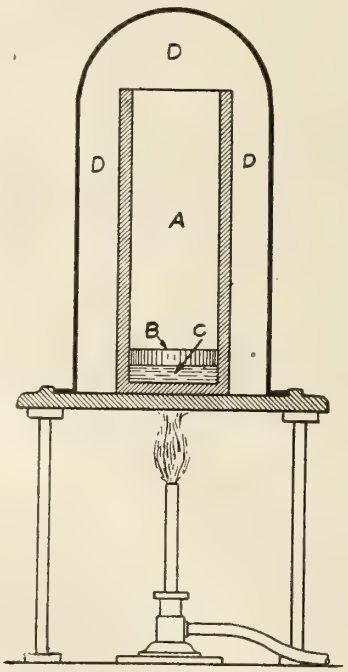
THE following article, which gives a very clear definition of the term "supersaturated steam," is reprinted from the Locomotive, a little monthly published by the Hartford Steam Boiler Insurance Co. The article seemed to us to cover the matter so clearly that we pass it on to our readers, feeling it may help some one to a better understanding of a term much used, but not always clearly understood.

The terms "wet steam," "dry or saturated steam" and "super-heated steam" are so familiar to every one who has but a slight acquaintance with water and its vapor that it would seem unnecessary to say anything further in regard to them. But now that we are hearing a good deal of the term "supersaturated steam," indicating, as it does, a condition of vapor somewhat unique, it may be well, before we discuss this condition of steam, to hark back to some first principles.

Let us suppose that we have an apparatus as shown in fig. 1 which consists of a cylinder A which has a piston B of an ideal nature such that it fits the cylinder perfectly and yet will move with absolutely no friction. Its weight is such that it will exert a pressure of 14.7 pounds on each square inch of the surface of the water C. We will suppose also that the water weighs exactly one pound. All the air has been exhausted from the surrounding space D so that the only pressure that can be exerted on the water will be 14.7 lbs. per square inch. By the nature of the arrangement the pressure will always be constant at 14.7 lbs. per square inch and cannot change as long as the piston is within the cylinder A. We will assume further that we have some means of supplying heat to the water as indicated in the sketch. If we start with the water at the temperature of 32° Fahrenheit and add heat to it the water will increase very slightly in volume, but will still remain a liquid until the temperature of 212° is reached. At this point, if we continue to supply heat, the temperature will remain constant at 212° and the water will begin to change from a liquid to a vapor. It will continue to follow this change with a very rapid increase of volume at a constant temperature until the water is all vaporized. When and just when the vaporization is complete the volume occupied by the vapor will be 26.79 cubic feet. Of course, to do this, our apparatus would necessarily have to be of somewhat different proportions than indicated in the sketch. We will now have in our cylinder one pound of dry saturated vapor. We will have in that space occupied by the vapor a definite number of molecules or particles of extremely minute size, although we shall not attempt to state the exact number.

If we continue to add heat to the vapor it will continue to increase in volume and it now also will undergo a temperature rise. It is no longer "dry saturated steam" but "superheated steam" and if we raise the temperature of it to 262° F. it will be 50° higher than when it was "dry saturated" and we would speak of it as being "steam at 14.7 lbs. and 50° superheat." Since the total number of molecules has not changed but the volume has increased it necessarily must be true that each cubic inch of the superheated vapor contains a smaller number of molecules than did a cubic inch of the saturated steam.

If now we cool the steam it will return to the dry saturated condition and if we cool it still further it will begin to condense and this condensation will continue until it returns to its initial condition of a liquid. In the condition in which it exists between dry saturated steam and a liquid it is known as wet steam or, more correctly, as wet saturated steam. This latter term, that of wet saturated, might appeal to us as incorrect. Actually, however, it is entirely proper. The steam in this condition consists of a mixture of a vapor and a liquid. The liquid may be present as a spray or mist or it may exist as one body of water. The vapor part, however, is still a dry saturated vapor. Each cubic inch of the vapor contains just as many molecules as it did when the entire pound was "dry saturated." This term, saturated, is a very good one. It means that we have put into a cubic inch of the vapor as many molecules as can conveniently be placed in that volume. In other words, we have saturated the cubic inch with water vapor molecules.



ILLUSTRATING HEAT ABSORPTION

Using the same apparatus we might have had a piston that would have exerted a pressure of 100 pounds per square inch. We would have found, under this condition, that the water could not exist as dry saturated steam until the temperature was raised to 327.8° F. For this steam to be superheated 50° the temperature would have to be 377.8° F. And in the same way we would find that for every other pressure that we might impose there would be a corresponding temperature for the dry saturated steam.

It is important to note that the temperature of the dry saturated steam and of the wet saturated steam is the same. The vapor and the liquid are both at the same temperature and, provided no heat is removed from or added to the mixture, they will remain indefinitely in the proportions in which they are existing. If 75% of the pound is vapor and 25% is liquid then the mixture is known as 75 per cent. "quality" steam. This condition of both vapor and liquid being at the same temperature with no tendency to change in relative proportion is known as "thermal equilibrium." There is no more tendency to heat to leave the vapor and enter the liquid and thereby vaporize that liquid than there is for heat to pass from the liquid to the vapor.

As a further illustration of what is meant by thermal equilibrium we may consider that we have a vessel filled with vapor at a given temperature and pressure. If we introduce some water the temperature of which is lower than that of the vapor into this vessel some of the vapor will condense until it has given up enough heat to raise the temperature of the liquid to that of the vapor. If the water is at a temperature higher than the vapor then some of the water will vaporize until the temperature of both becomes the same.

This idea of thermal equilibrium plays an important part in super-saturated steam. It might be said at this point that the condition of super-saturated steam is an unusual one in that it is a very unstable condition. While scientists long have known of the possibility of its existence it has not generally been supposed that it would be found in practice to any appreciable extent.

In order to appreciate this condition of supersaturation it must be fully realized that when we have thermal equilibrium the water vapor at any pressure must have a perfectly definite and easily determined temperature. Furthermore, if it is dry saturated, it will occupy a certain definite volume known as the Specific Volume. If it is 50 per cent. wet it will occupy very nearly 50 per cent. of the Specific Volume.

In investigating the conditions under which steam turbines operate it has been found repeatedly that if a pressure gauge and a thermometer are used to read the pressure and temperature of the steam in the exhaust passage the thermometer will read a temperature several degrees below the value corresponding to the pressure. If thermal equilibrium existed

no such discrepancy in readings could exist. The condition has sometimes been spoken of as "under-cooling" and this term is a very good one. As a matter of fact the vapor is lower in temperature than it would be under equilibrium conditions for the observed pressure. And yet it is a difficult matter to obtain the exact temperature of the vapor. The thermometer, if placed in a pocket where it will be protected from the rush of the steam, will soon be covered with a film of moisture due to condensation of the vapor. Condensation of the supersaturated vapor under these conditions will always occur because, as has been said before, this unique condition is a very unstable one. The vapor will always tend to return to a condition of thermal equilibrium with the condensate and the thermometer mentioned above will therefore read very nearly or exactly the temperature corresponding to the observed pressure. If, however, the thermometer bulb is exposed to the high velocity steam the film of moisture will be swept away and the molecules of vapor which are at the lower temperature will be given an opportunity to register their true value. Even this method of taking the temperature must give only approximate results.

While the above discussion of "undercooling" serves to bring out some remarkable facts concerning supersaturated steam it does not give us a conception of just what is meant by the term "supersaturation." An attempt will now be made to explain this term.

The conditions under which steam flows through a nozzle and the theoretical laws which govern this flow have long been known. These laws had always been considered very exact and absolute. It was thought that the actual flow of steam through a nozzle would have to be less than the theoretical on account of friction impeding the flow. When, however, tests showed that the actual flow of the practically dry steam used in the tests was greater than the theoretical it was realized that something unusual had occurred. At first it was thought that moisture in the steam was the explanation of the greater weight discharged. But when calculation determined that from 10 per cent. to 20 per cent. moisture would have to be present to give the results obtained it was realized that some other explanation must be secured. Since the weight discharged must be in direct relation to the number of molecules passing in a given time the only possible solution is that the vapor must carry more molecules per cubic inch under the actual conditions of flow than when the unit volume is "saturated" with molecules. In other words, the unit volume is "supersaturated." As an actual fact we do not know how many molecules it would be possible to crowd into a unit volume but we do know that only a certain definite number will stay there naturally and with this number in the unit volume the steam is saturated. Note that this is the only natural condition in which vapor will exist. While it may become supersaturated it will very readily and upon the slightest disturbance revert to the saturated state with consequent condensation of its excess molecules and when this change is effected thermal equilibrium will be established.

The subject of supersaturation is one that is demanding very close study by the steam turbine designer. The matter has been the more forcibly brought to the attention of engineers and scientists in this field by an article entitled "A New Theory of the Steam Turbine" by H. M. Martin in Engineering (London), Vol. CVI. Mr. Martin brings out the point that reciprocating engine design has been largely cut and try methods with theoretical considerations giving aid only in a most general manner. The varying conditions in different engines such as temperature changes within each cycle of operation, valve leakage and clearance have been most difficult of correlation between any given engine and a new design. It is true that theory has been largely by cut and try methods, possible but the gap between theory and practice has been a wide one. The steam turbine, however, has lent itself most favorably to theoretical design. Predictions of the performance of a given design have been possible to a remarkable exactness. Even here considerable experience has been necessary to determine certain correcting factors for discrepancies between theory and practice. Mr. Martin suggests that some of these apparent discrepancies may be explained by the fact that the steam is supersaturated during all, or very nearly all, of its passage from the nozzle to the condenser.

The variable quantities encountered in an investigation of this nature are many. It would seem almost impossible to develop formulae for use in design. Similar obstacles have arisen in the past, however, and sooner or later have been surmounted. It is therefore confidently expected that the investigators in this field will reach a complete and satisfactory solution of the whole problem.

WILL NOT PAY IF POWER IS CUT OFF

Toronto Firm Says It Is Almost Impossible to Go On Under Present Conditions

Following is copy of a letter sent to the Board of control of Toronto: "It is absolutely impossible to do business on this basis," stated the firm, "and unless some definite arrangement can be made we will have to shut down entirely. Our business is quite slack and we have cut down from 65 to 15 or 20 employees, and while we do not care to be obliged to handle it in this way, we would much rather have our power, say four days a week, and none at all the other three days. We should imagine that other companies would be in the same position. We are today advising our men that from now on we will not pay them for the time for which the power is cut off."

TO GUARANTEE THE COMPANY'S BONDS

Town of Paris to Lend Aid to the MacFarlane Engineering Firm

A proposition has been made to the Paris, Ont., Council by the MacFarlane Engineering Company for the municipality to guarantee bonds for the firm to the amount of $40,000. A committee appointed to investigate made a highly favorable report to a special meeting of the Council as regards the security offered. There were also present some thirty representative members of the Board of Trade, of whom a number spoke in favor of the adoption of the offer. On request of Mayor Patterson, a unanimous vote was passed to support the Council in the movement. A by-law has been prepared and will be submitted to the ratepayers early in December. The firm has already some 75 or 80 men employed, and it is confidently expected that within a few months after the passing of the by-law 200 men will be on the pay roll.

INCORPORATIONS

The Superheater Company of Canada, Transportation Building, Montreal, and with works at Sherbrooke, Que., has been incorporated to manufacture steam superheaters for all classes of service. The company is giving special attention to locomotive, marine and stationary equipment and have Canadian rights for manufacturing the "Electo" Superheater. Equipment for stationary power plants is designed to suit each installation and this is particularly true in case of stationary power plants, the superheaters being applicable to any type of water or fire tube boilers. Superheaters of the type manufactured by this company are now in general service in locomotive and marine and stationary plants throughout the world. The company uses a patented form of bending the tubing in its superheater which is termed a forged return bend which is formed from the metal of the pipes themselves without any autogeneous welding. This is also being largely sought after for use in various styles of pipe coils and condensers.

G. M. Arnold, for the past ten years Ontario's Government inspector of boilers, died in Toronto, and the funeral was largely attended. Mr. Arnold, who was very widely known and highly esteemed, had been previous to his government appointment for some twenty years with the Niagara Navigation Company.

A NEW CHAIRMAN APPOINTED

THE appointment has been announced of Mr. J. M. Brown, in succession to the late Mr. W. C. McGhie, as chairman of the Board of Examiners of Stationary Engineers for the Province of Ontario. The new chairman brings to the position qualities of practical and technical experience which should help materially towards his success in a situation which is more arduous than is sometimes thought. Mr. Brown is a native of Ontario, having been born in the town of Fergus. He entered the School of Practical Science of Toronto University in the year 1899, and graduated three years later. He entered the drawing office of Webster, Campbell & Lane, of Cleveland, which firm later became the Wellman, Siever, Morgan Co., and remained with them about one year, leaving there to enter the employ of the Westinghouse Machine Co., Pittsburgh. In 1908 Mr. Brown came to Toronto to instal the high-pressure turbines in the John Street Pumping Station, and after completing the installation remained for about one year with them. He then returned to Pittsburgh and remained with the Westinghouse Co. till 1914, when he went to the Nobel munition plant, installing and operating the steam turbines used there. From there he went to the East End station of the Dominion Power Co., Hamilton, again being connected with steam turbines, and remained in that position till his appointment to the Board of Examiners a few months ago.

In Mr. Brown and Mr. Mosely the Board have two men who know the engineer's problems from the viewpoint of actual experience. This is a good feature, both for the public and for the engineer who comes up for examination. He will be assured of sympathetic treatment, and will have the satisfaction of knowing that the men who are examining him know exactly what is required, and will not reckon his ability from a purely academical standpoint.

Adequate Boiler Inspection

IN an article published in the Toronto Star Weekly the Hon. W. R. Rollo has something to say on the subject of making labor safe. In connection with this, he states, there is a demand for the inspection of every boiler in the province, in addition to the insurance inspection. Mr. Rollo intimates that this demand among others will probably be met.

While we are entirely of the opinion that every boiler should be inspected, we can see no reason why a boiler owner who wishes to carry insurance should be penalized by two inspections. If he carries no insurance, then the Government should undertake the inspection in the interest of the public and at the owner's expense. Where the owner carries insurance, an inspection is made by the insurance company's inspector, who is generally, at least, as capable as the Government inspector. Getting a boiler ready for inspection is a matter entailing time and expense, and whereas an insurance company usually make their inspection fit the owner's convenience, this will hardly enter the Government official's mind. In many cases the insurance company make their inspection at a time when the factory is closed down, and the boiler opened up for cleaning in the ordinary way.

The Province of Quebec makes every insurance inspector carry a Government certificate of competency as a boiler inspector, and holds regular examinations for candidates for these positions. Having given this certificate, the inspector has all the status of a Government official as far as his reports and inspections go. Most large and many small concerns carry insurance for the protection it gives them. To compel them to submit to two inspections would be inflicting an unnecessary hardship.

"I Wonder if he Has Really Reformed?"

Gas Engine Drive and Turbine Pumps

The Pumping Work of a Large Dry Dock is Very Efficiently and Economically Performed by Gas Engine Running on Producer Gas, Showing the Possibilities of This Type of Prime Mover*

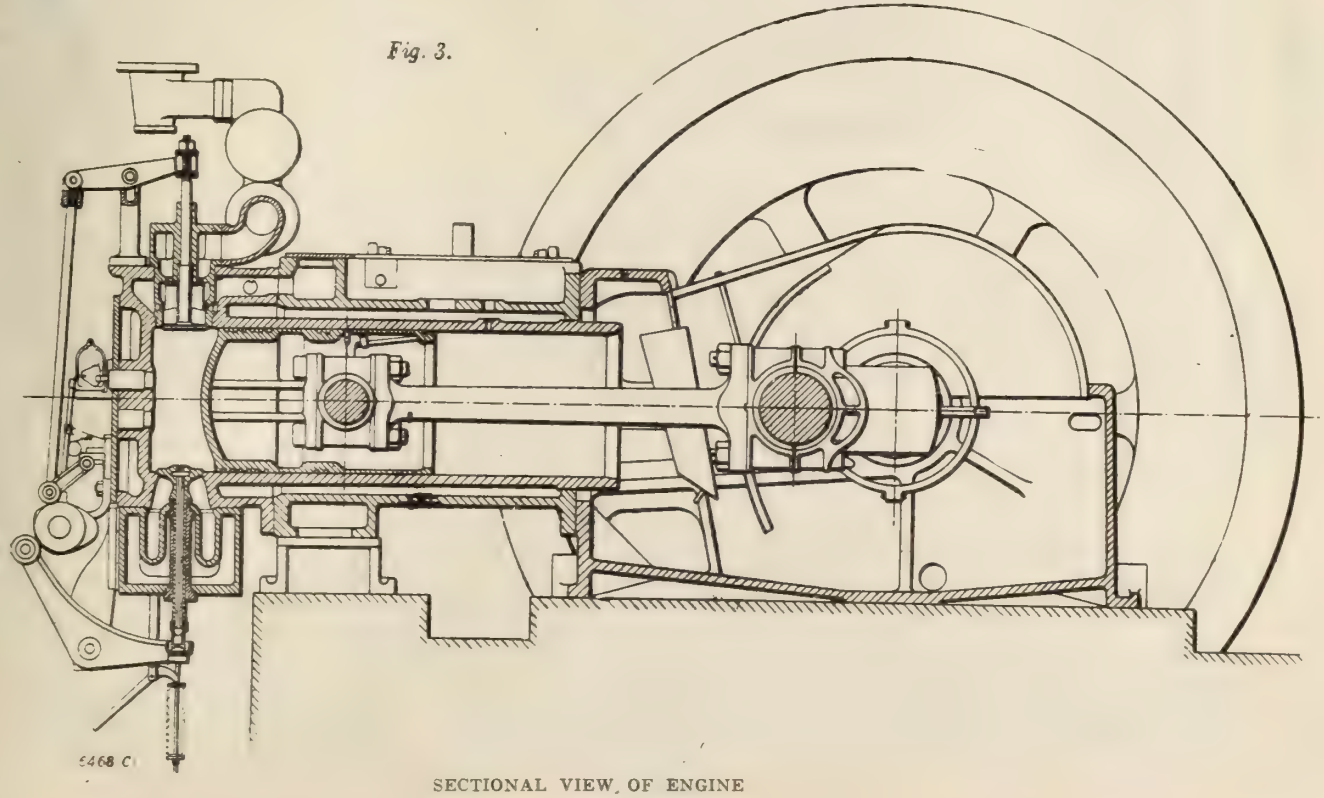
DURING a critical period of the war, the engineers for the Port of London Authority were called upon materially to reduce the time required to pump out the dry docks at Tilbury, which were then being used for the examination and repair of torpedo craft and other vessels for the Admiralty. It was recognised that the existing steam pumps had become obsolete and needed replacing. A thorough investigation was, therefore, made into the respective merits of centrifugal pumps driven either by "gas," "oil" (Diesel) or "steam" engines, and the decision was given in favour of gas engines to operate from producer gas, and using anthracite as fuel. Two sets of multi-cylinder gas engines were built and installed by the Premier Gas Engine Co., Limited, Sandiacre, near Nottingham (now associated with Messrs. Crossley Brothers, Limited, Manchester). Each engine is coupled directly through its crankshaft to a centrifugal pump made by Messrs. Gwynnes, Limited, of Hammersmith. By the courtesy of Mr. C. R. S. Kirkpatrick, chief engineer to the Port of London Authority, we are able to illustrate and describe this interesting plant.

A diagram of the performance of the pumps and a general lay-out of the installation are given in Figs. 1 and 2 on this and the opposite pages, while Fig. 3, on the opposite page, is a cross-section of one of the engines. As will be seen from these illustrations the engines and pumps are arranged in a deep pit, or chamber, forming an engine room with sloping walls. The general appearance of the plant is well indicated in the general views given in Fig. 4 and Fig. 5, on page 534. By sinking the pumps in this manner the suction is materially reduced, and under certain tidal conditions a drowned suction is obtained. This latter makes it possible to obtain the maximum efficiency for the centrifugal pumps. The water enters each pump through piping connected to large drainage culverts arranged below the engine-house floor, and in communication with the various docks to be de-watered. The Gwynne pump impellers are of the double-inlet type with shrouded vanes, smooth finished and carefully balanced. The charging of the pumps, when necessary, is effected by electrically-driven duplex wet vacuum pumps made by Messrs. F. W. Brackett & Co., Limited, Colchester. These pumps are gear-driven, the gear-box being so arranged that when the pumps are working on vacuum only, they operate at a speed of 92 r.p.m. When it is desired that the pumps should run pumping all water, the ratio of the gears is such as to obtain a reduced speed of 18 r.p.m. A charging pump is provided to each main centrifugal pump, these charging pumps being erected one at each end of the engine-house, as may be seen in Fig. 4 and Fig. 5.

Prior to installing the gas-driven pumping sets the engine-house contained four sets of steam-driven pumps, and the positions of the centrifugal pumps were determined by the existing delivery pipes, which pass through one side of the chamber and are connected with the open channel or discharge pit. Two of the four original pipes were made use of, and the remaining two were blanked off. The delivery from the centrifugal pumps is coupled with a large sluice valve which has a graduated indicator plate above, showing the exact amount of opening at the sluice valve. The opening and closing of this valve is operated by hydraulic pressure at 500 lbs. per square inch to 750 lbs. per square inch, and controlled by slide valves on the supply pipe from the hydraulic main. The sluice valves are each 44 in. diameter, being of the full-way wedge-gate type, made by Messrs. J. Blakeborough & Sons, Limited, Brighouse.

Referring now in more detail to the main pumping sets, it may be said that these consist of two "Premier" four-cylinder horizontal gas engines, each of 368 brake horse-power at normal load, and connected by a flanged coupling on the engine shaft to a Gwynne Invincible centrifugal pump. The speed is 200

Fig. 3.



SECTIONAL VIEW OF ENGINE

r.p.m. The gas-producing plant comprises three separate units, one of which serves as a stand-by. They were made by the Power Gas Corporation, Limited, of Stockton-on-Tees, and are of the "suction-pressure" type with the usual complement of scrubbing apparatus. The gasplant house is situated about 50 ft. away from the engine-house, their relative positions being shown in Fig. 2. The gas from the producer plant is drawn through the washers and coke scrubbers by an exhauster fan, which also forces the gas, at a pressure of a few inches, through the dry sawdust-scrubbers and into the gas main leading to the engine-house. Starting is by compressed air, and with gas ready at the plant, starting from cold to operation at full speed occupies less than five minutes.

In determining the pump capacity required, it was stipulated in the Port of London Authority's specification that both pumps operating together should be capable of de-watering the Tilbury Western Dry Dock in three hours, or with one set in six hours, when the dock contained 1,825,000 cub. ft. of water. In actual practice the volume of water in the dry dock depends on the height of the water in main dock. The following figures are interesting and show the results of careful tests made in this direction.

Test No. 1.—One centrifugal pump emptied the large dock in four hours 50 min., when containing 1,680,000 cub. ft. of water.

Test No. 2.—Two centrifugal pumps required 2 hours 40 mins. when the dock contained 1,639,000 cub. ft. of water, and working against the highest tide, 12 in. higher than T.H.W.

In the case of Test No. 1 this gives a discharge rate of 5,793 cub. ft. per minute—against a variable head of minus 1 to plus 29 ft. (30 ft. total). Test No. 2 gives 10,244 cub. ft. per minute against a variable head of 5 ft. to 33 ft. (28 ft. total). Fig. 1, annexed, is a reproduction of a pumping diagram showing the pump volumes, static and gauge heads, to which the plant had to conform. The chain-dotted line has been plotted from a large number of tests taken during the runing of the sets and represents the average actual volume of water pumped, with one pump only working.

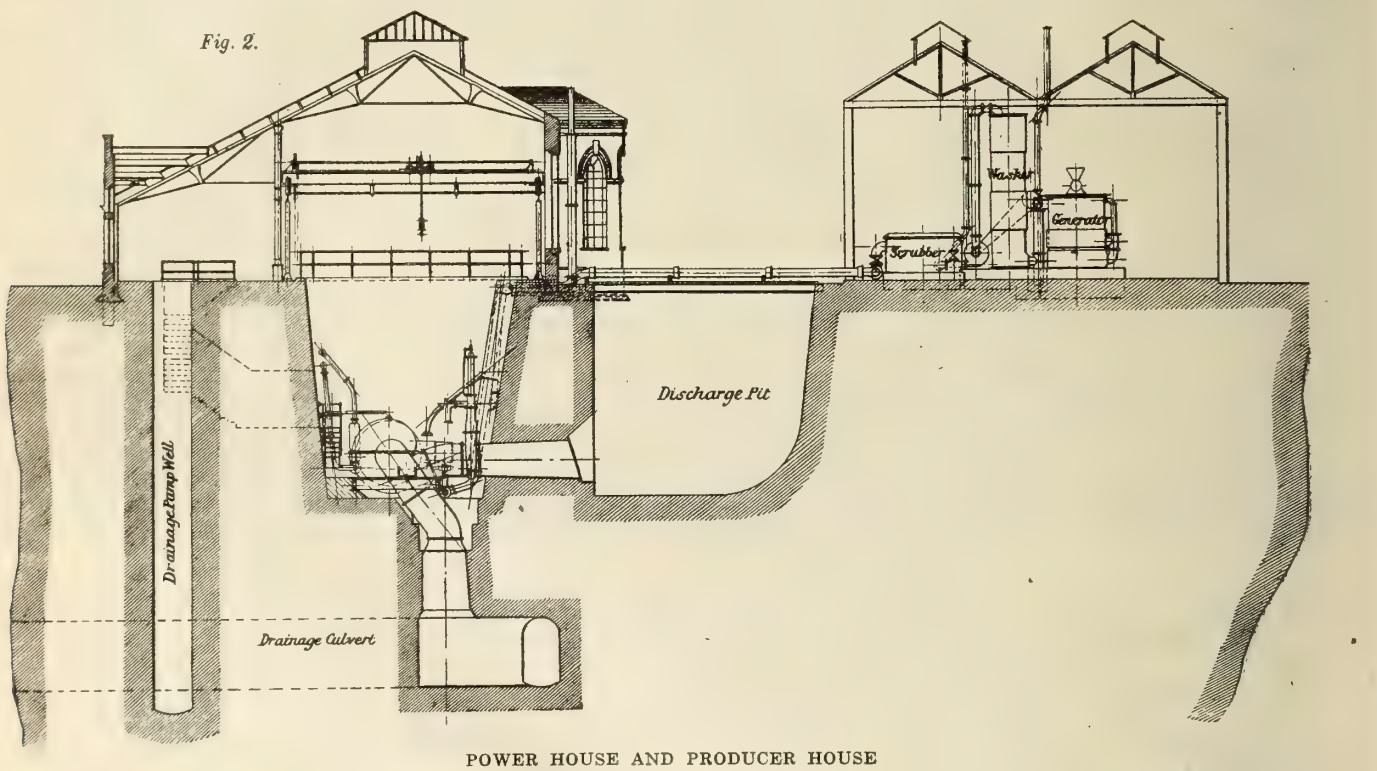
Mention has already been made that compressed air is used for starting the main engines. The air-compressing plant is by Messrs. Reavall & Co., Limited, Ipswich, and of the quadruplex cylinder type, belt - driven (using a jockey pulley) from a 10 h.p. electric motor. The sets are in duplicate, each compressor having a capacity of 36 cub. ft. of free air per minute. The air is delivered at a pressure of 200 lbs. per square inch into a riveted steel reservoir, which, as shown in Fig. 5, is carried on brackets from the engine-house wall. The cooling water circulated through the gas-engine jackets is provided by pumps driven from the end of the main centrifugal pump spindles.

In the "Premier" multi-cylinder gas engine the governor and side-shaft, shown in the foreground in Fig. 4, are on the free side of the engine, i.e., on the side away from the flywheel. The governor is of the enclosed centrifugal spring-loaded type, highly sensitive, and is directly driven by skew gears from the engine shaft. The governor controls the admission of gas by means of a central throttle valve and is actuated from a weigh-shaft and connecting-rod coupled to the governor lever. The gas after passing through the throttle valve enters a gas manifold pipe coupled to each of the four cylinders through the admission-valve cages. Air enters separately, so that the gas and air, forming a mixture, only unite inside each admission-valve cage and immediately behind the point of entry into the cylinder. In the event of an occasional back-fire occurring in any one cylinder, this does not disturb the mixture entering the remaining cylinders, and so the governing is not upset. The gas throttle is specially designed to ensure good control and made easily removable for cleaning purposes. In addition, an air throttle valve is provided to each cylinder, so that, if desired, the strength of the firing mixture can be separately adjusted for each cylinder.

The design and construction of cylinder, combustion-chamber, valves, and cam-operating gear of the engine are clearly shown in Fig. 3. As may be seen, the combustion-chamber is symmetrical in shape and quite free from pockets. The admission valve is large to ensure a full charge entering the cylinder. The exhaust valve, which is placed at the lowest point of the cylinder, is also of liberal proportions to ensure effective discharge of the products of combustion. The shape of the combustion-chamber is such that the clearance volume, when the piston is on the back centre, offers the minimum surface area to the cooling action of the jacket water—thus contributing to the thermal efficiency of the engine. Notwithstanding this, the water passages are ample and give effective cooling where it is most needed.

The design of the cylinder calls for special comment. It will be observed

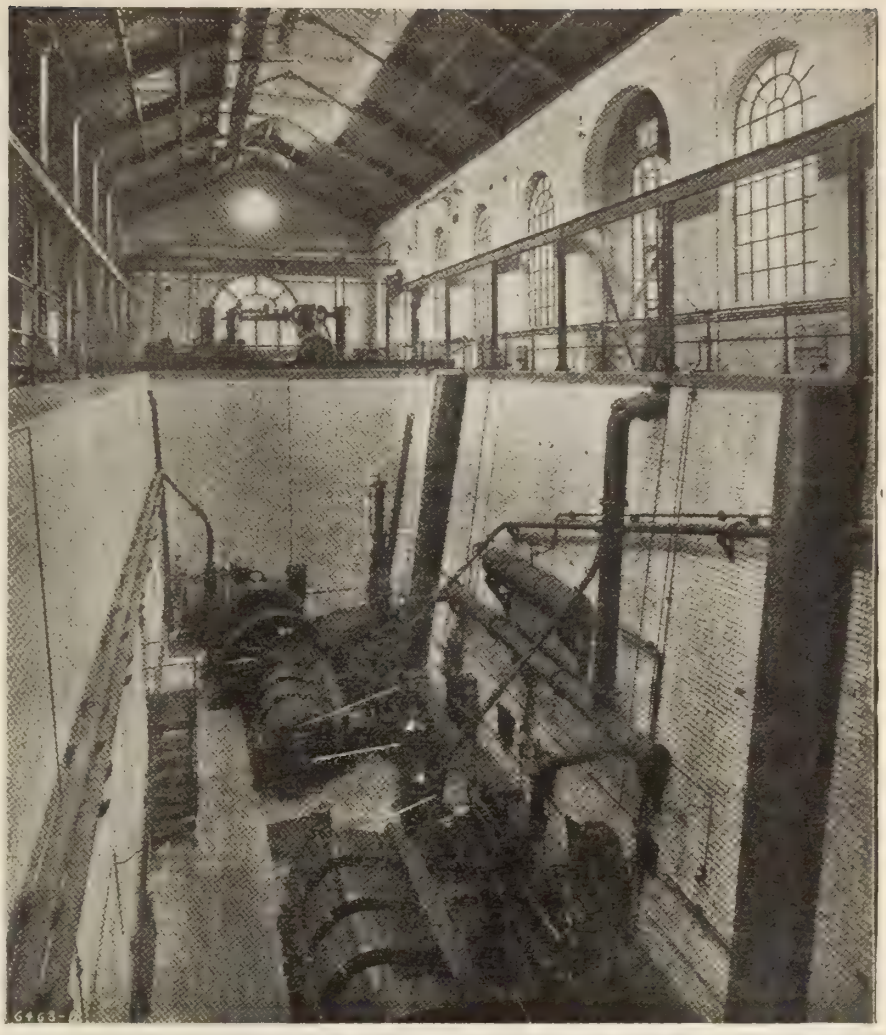
Fig. 2.



POWER HOUSE AND PRODUCER HOUSE

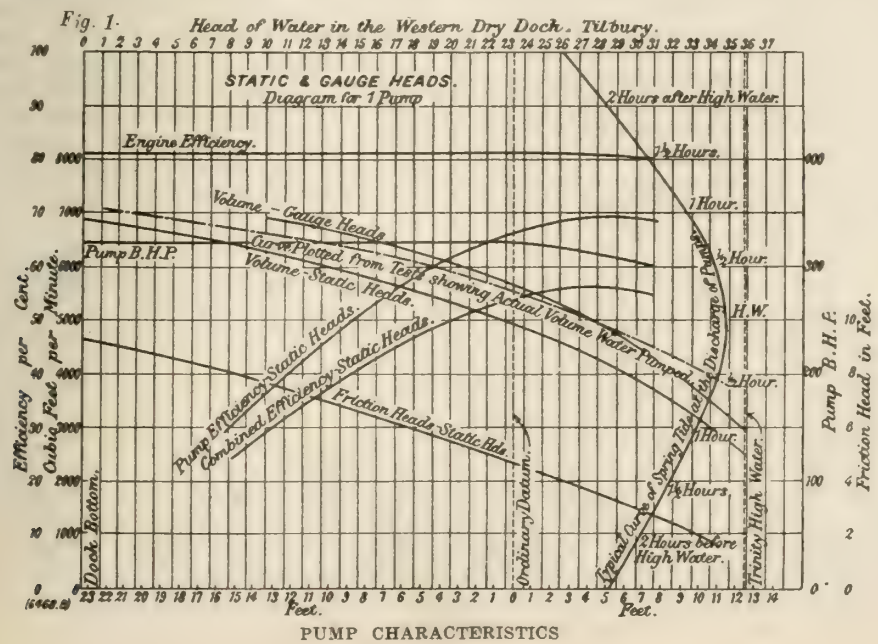
that this engine has no loose liner—such as is generally understood by that term. The cylinder and breech end are cast integral, and form one plain casting, thus dispensing with the liner joint which is by far the most difficult joint to make and keep tight upon a gas engine cylinder. The advantage claimed for a loose liner is that it can be made of specially hard close-grained cast-iron which is easily renewable when worn. Against this may be instanced the large number of worn liners directly caused by a faulty and leaking liner joint. With the "Premier" design as we have said there is no loose liner, but, on the other hand, the cylinder barrel with breech end form so simple a casting that this can also be made from close-grained metal to withstand wear, and be suitable alike for the cylinder-wall surface and exhaust seating. The back of the breech end is cast open, giving perfect access in the first place for the removal of cores and cleaning the casting. A large cover plate as shown is afterwards attached at the back, which allows for the free expansion of the inside walls when working under heat stress. As the result of this method of construction, cracked or broken breech ends are claimed to be an unknown quantity upon the "Premier" gas engines.

All valves are operated from a cam-shaft running in self-oiling bearings, arranged behind the cylinders and placed so that the breech-end cover-plate previously referred to, can be removed without disturbing the cam-shaft. The removal of the cover-plate affords perfect access to the interior of each water-jacket for cleaning away scale or sediment which usually forms around the hottest portion of gas-engine jackets. Each inlet-valve cage is complete with a gas valve and an admission valve, and fits inside a bored opening at the top of the cylinder. The seating is made with a metal-to-metal ground-in joint, so that the complete inlet-valve cage can be removed quickly. The exhaust valve is placed as shown directly below the admission valve, and is also readily removed through the same top opening. This exhaust valve is water-cooled by means of an internal pipe, passing up the hollow valve spindle, through which cold water passes directly to the head of the valve. Ignition is by low-tension magneto operated by eccentrics driven from the cam-shaft, the timing being adjustable whilst the engine is working. The ignition-plug is placed directly above the centre and at the back of the combustion-chamber, this being the best position to ensure perfect firing of the mixture. Immediately below the ignition plug-hole is arranged the opening for the compressed-air starting valve. The gear for starting up the gas engine by compressed air is fully automatic, consisting of a cam-operated distributing valve which admits compressed air to the cylinders at correct intervals. The gears operating both side-shafts and cam-shaft are of the skew type running in oil baths.



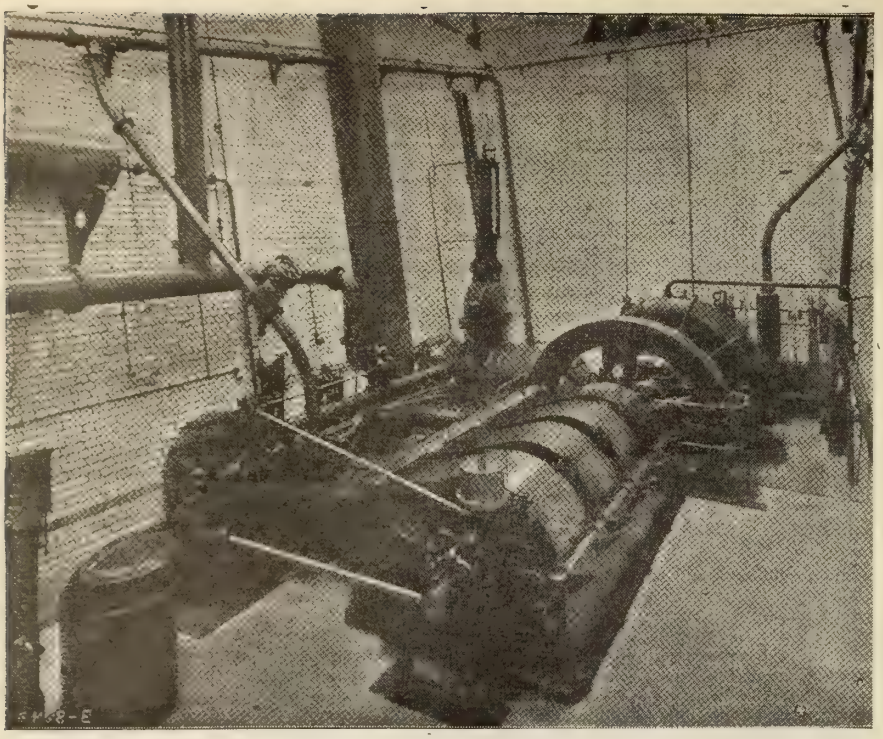
THE PUMPING PIT

Fig. 1.



PUMP CHARACTERISTICS

It has been stated at times that the enclosed type of gas engine arranged with forced lubrication is wasteful in regard to oil consumption. Certainly this does not apply to the "Premier" engine, and the engineer at Tilbury Docks testified as to the moderate quantity of lubricating oil used for all purposes on these engines. The supply is by means of an oscillating valveless pump driven



ONE OF THE UNITS

from the end of the side-shaft, the oil being delivered into boxes placed over each main bearing, and afterwards flowing through by gravity. The quantity of oil delivered into each box can be regulated by hand, and set so that the oil passing to the main and crank-pin bearings is not more than to meet actual requirements. Otherwise, with an enclosed engine there is some possibility of surplus oil lubricating thrown off from the connecting-rod ends, entering the cylinders in excess, and so getting past the pistons into the combustion-chambers, where it is wasted. Tests taken over a period of one month show that only 2-6 gallons of lubricating oil are used per 24 hours. This works out at the rate of 0.0024 of a pint per brake horse-power hour at full load. Part of this oil is recoverable after passing through a filter, and may be used again for shafting lubrication and the like. We are informed that careful tests over long periods show less than 3 cwt. of fuel is used per hour at the producer-gas plant per engine. This is approximately 0.9 lb. per brake horse-power at full load. Calculating the cost of this fuel at 50s. a ton, it works out at 0..24d. per brake horse-power hour.—Engineering.

TRADE GOSSIP

That Collingwood Plant.—The Collingwod Steel plant has caused a lot of worry to Collingwood town council and to many of the citizens as well. It was lately reported that the plant was to be scrapped and on Monday last when it was found that a couple of freight cars had been put on the siding at the plant, it looked as if this were so. The town immediately stepped in and attached the plant for taxes, $64,000, is the amount alleged to be due the town. The seizure was made and thus the movement of the machinery and equipment was staved off for a few days at least. The mayor went to Toronto to consult with the owners, and the result of the interview is not yet known. The plant is a big one and until a few months ago it was owned by Wm. Kennedy and Sons, of Owen Sound. The plant was in commission during the war and turned out a very large amount of steel for the making of munitions.

Better in Hamilton.—Except for the steel mills in Hamilton the coal shortage is causing no great worry there. The majority of the plants are able to get along during the summer without coal, using power to run the plants, says a Hamilton report. And as for the steel plant, officials there state that at present there is no probability of closing through lack of coal. The other plants, using the little they do, report that they are quite prepared for a shortage, and, unless the shortage happens in the winter, will not be seriously affected by it.

Brantford Needs Power.—There is considerable worry on the part of Brantford officials owing to the inability to secure Hydro power. It is pointed out that several new industries have been landed for Brantford, and are nearly ready for production, but the Hydro Commission will accept no more new customers, and power cannot be got. Ald. F. C. Harp, chairman of the Fire and Light Committee, declared that a special meeting of the City Council would be called shortly, and a fight would be initiated to secure a supply of power even if other interests had to suffer for a time.

Bought New Plant.—Messrs. Langslow, Ltd., Canadian branch of Langslow Fowler, Rochester, N.Y., are equipping a factory in Cobourg for the manufacture of all kinds of school furniture. The Canada Machinery Corporation report having secured the order for all of the wood-working machinery required.

Bought Part of Plant.—Part of the equipment used at the Polson Works, Toronto, has been disposed of, a large amount going to the A. R. Williams Machinery Co. They took in drills, slotter, planer, several large lathes, shaper, drills, gear cutters, etc. The plant is in liquidation and there is still more of it to be disposed of.

Starting New Business. — Holden-Morgan Co., Toronto, are remodelling their plant with a view of specializing on the rebuilding of automobiles. It is their intention to take in cars that have been more or less worn, and rebuild the worn parts, any make of car being taken. Some of the surplus machine tools that were used in the shop previously have been disposed of.

Deal Completed. — The change announced some time ago has been completed whereby the Whitman & Barnes plant, one of the oldest and largest industrial concerns in St. Catharines, has been taken over by J. H. Williams & Co., with plants at Buffalo and Brooklyn. The United States plant will serve the U.S. market, and the St. Catharines plant the Canadian and export trade.

Appointed New Officers.—At a meeting of the directors of the Federal Engineering Co., Ltd., November 3, 1920, Col. F. H. Deacon was elected president of the company. J. W. Campbell, who has been president of the company since its inception, resigned, as he has been living in California for some years. The other officers and directors of the company are: R. G. Black, vice-president; Lieut.-Col. H. L. Edmonds, secretary-treasurer; S. C. DeWitt, manager; A. A. Bowman and J. E. Murphy, directors.

PERSONAL

Mr. J. M. Brown has been appointed chairman of the Stationary Engineers' Board of the Province of Ontario, in succession to Mr. W. C. McGhie, deceased. The appointment was made by Hon. Walter Rollo.

The Owen Sound Board of Trade tendered a complimentary banquet to H. B. Smith, vice-president of the British Empire Steel Corporation, who recently removed from Owen Sound to Toronto. During the evening he was presented with an illuminated address from the Board of Trade and City Council.

Electrical Supplies

The PIERCE RENEWABLE FUSE is shown above. This illustration does not in the least exaggerate the simplicity of the Pierce Fuse—A blown Pierce Fuse can be renewed and put into the circuit in 15 seconds. It's a wonderful saver of time and trouble.

SQUARE D. SAFETY SWITCH—an absolute safeguard against shock, fire and accident of any kind. This is a simple knife switch, housed in pressed steel, with the handle on the outside where the current cannot reach it. The Square D. Safety Switch is made in a variety of sizes and types and capacities—for factories, office buildings and homes.

All electrical equipment sponsored by Fairbanks-Morse is of superior quality and design and insures efficiency, safety and durability in service.

FAIRBANKS-MORSE

Engineer Wanted

Applications for the position of Engineer in Charge of the Brandon Water Works Pumping Station will be received by the undersigned until November 27th, 1920. Duties to commence on or about December 1st, 1920.

Applicants must hold a first-class steam engineer's license, Province of Manitoba, and should be familiar with pumping machinery.

A residence with heat and light are provided in addition to salary.

Applicants will state salary asked, give an outline of their experience and name their references.

Further details regarding the position may be had from J. M. Begg, City Engineer, Brandon, or from W. M. Scott, Consulting Engineer, Winnipeg.

(Signed) HARRY BROWN,
City Clerk,
Brandon, Man.

SITUATIONS VACANT

WANTED — EXPERIENCED BOILER DESIGNER by large manufacturing plant in Ontario. Apply Box 92120, Power House. (p12h)

WANTED—A1 GENERAL BLACKSMITH FAMiliar with mine and mill work; permanent position. Apply, mentioning "Power House," stating experience and wages wanted, to Moose Mountain, Ltd., Sellwood, Ont.

EMPLOYMENT DESIRED

STATIONARY ENGINEER, SECOND-CLASS, requires position; thoroughly experienced with water-tube and return tubular boilers, Corliss and all classes of stationary engines compressors, electric motors and generators; heating systems and hydraulic. Apply, mentioning "Power House," to No. 67062, A. Wright, 298 Bathurst St.

RETURNED SOLDIER — EXPERIENCED painter, electrician and elevator operator, or other suitable employment; desires work at once. Apply mentioning "Power House," to Pte. (163466) Ira Charles Winckler, 83 Carlton St., Toronto.

RETURNED SOLDIER WANTS WORK—ANY kind; used to steam heat boilers. Apply, mentioning "Power House," to W. Greenfield (33065), 34 Brock Ave., Toronto.

GREAT BARS

ALL STYLES TO ORDER—PROMPT DELIVery. The E. T. Lansdowne Foundry Co., 37 Niagara St., Toronto. Mention "Power House."

BELTING

4½—4-PLY NEW CANVAS STITCHED BELTing at 30 cents per foot. We carry a complete stock of belting, pulleys and mill supplies. Apply, mentioning "Power House," to N. Smith, 138 York St., Toronto.

LEATHER AND RUBBER BELTING, USED, but in good condition; at about half new price. Apply, mentioning "Power House," to Tarshis & Sons, 400 Front St. East, Toronto.

WE HAVE A QUANTITY OF NEW RUBBER belting to sell at less than half price; will ship C.O.D., subject to inspection; new circular saws, good second-hand leather and rubber belting, wire cable, vises, chain blocks, garden hose, steam hose, rubber packing; send us your requirements; our quotations will surprise. Apply, mentioning "Power House," to The York Belting Co., 115 York St., Toronto, Ont.

EQUIPMENT

BOILERS, SMOKE STACKS, HOISTING ENgines, rock drills, grey iron castings. Apply, mentioning "Power House," to Napanee Iron Works, Limited, Napanee.

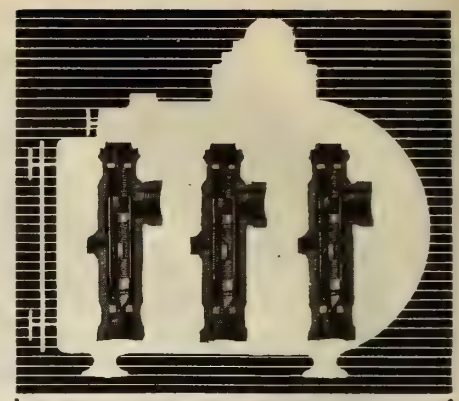
ENGINE PACKING, ENGINEERS' SPECIALties, pipe and boiler coverings, roofing. Apply, mentioning "Power House," to Eureka Asbestos Co., Toronto.

BOILERS AND POWER PLANT EQUIPMENT bought by the Henry Engineering Co. (Henry-Rumgay-McBryde), 71 Bay St., Toronto. Mention "Power House."

ROLLER BEARING FACTORY—DRY KILN, transfer, railroad and steamboat trucks, manufactured by the Corbet Foundry & Machine Co., Ltd., Owen Sound, Ont. Mention "Power House."

THE JOHN INGLIS CO., LTD., ENGINEERS and boilermakers. Write us for prices. 14 Strachan Ave., Toronto. Mention "Power House."

WE BUY IDLE EQUIPMENT OR MACHINery; call or write. Apply, mentioning "Power House," to H. W. Petrie, Ltd., Toronto.



3 Traps for Price of One

If you are willing to pay for mere *bulk,* you will surely get it in the cumbersome float or bucket trap with its impressive array of floats, levers, water gauges, bowls, toggles, packing and other superfluous parts.

But, if you are more interested in *results achieved* by a steam trap than in mere *size* of the apparatus—if you want *real* efficiency unimpaired by trouble-making mechanical contraptions, you will get exactly what you want *at one-third the price in*

STEAM TRAP SARCO

This is a *simple, compact* steam trap with all unnecessary mechanism eliminated. Therefore the Sarco occupies but a fraction of the space required by bucket or float traps. It can be installed at any point on the line without any change of piping. No platform, pit or support needed.

Steam Trap Sarco opens *promptly* to drain off the condensate—and closes just as promptly to prevent the loss of live steam.

Made in sizes from ⅜" to 3", and is guaranteed for pressures up to 200 lbs.

It *insures* you of greater efficiency, and at the same time permits you to save two-thirds of your steam trap costs.

Send for Booklet J-12 and particulars about the 30-day free trial offer.

Turbine Drive for Pumps

The De Laval Geared Steam Turbine has revolutionized pumping practice.

De Laval Geared Turbine-driven Centrifugal Pumps are to-day the most economical for practically all water supply purposes. Recognition of this fact in the municipal water works field has resulted in the installation of a very large number of De Laval pumping units, for all heads and all capacities up to 100 million gallons per day. Because of its (1) high efficiency, (2) comparatively small cost, (3) light weight, and (4) absence of vibration, which eliminates the necessity of heavy foundations, (5) small space requirements, reducing the cost of buildings, and (6) light parts, avoiding the necessity of heavy crane facilities, the De Laval Steam Turbine-driven Pump is able to show the lowest overall cost of handling water.

The same conditions apply to general service pumps, condenser circulating pumps, irrigation pumps, etc. The elimination of packings, valves and rubbing surfaces greatly increases reliability and reduces the expenses for attendance and repairs.

State conditions and recommendations will be made. Ask for catalog 100

Keep Up Steam Pressure by Shutting Out Cold Air

The inleakage of cold air through furnace walls records its effects on the gauge.

BETSON'S PLASTIC FIRE-BRICK prevents this leakage. It forms a monolithic wall, which neither expands nor contracts. Ordinary fire-walls last a few months, but BETSON'S PLASTIC FIRE-BRICK stands for years without cracking, a seal against outside air.

Re-line furnaces; mould one-piece baffles and repair cracks with BETSON'S PLASTIC FIRE-BRICK. Easily applied by anybody. Prompt shipments from warehouses in principal cities.

Write for information pamphlet.

MONCRIEFF'S
"UNIFIC" GAUGE GLASSES

The British Navy uses "Moncrieff's" "Unific". It is the kind that lasts.
It is a special feature of the "Unific" that it does not readily corrode; resists extreme changes of temperature and withstands the highest working steam pressure. In consequence it has a long life, justifies a higher price than the soda lime glasses, and is, indeed, the more economical purchase in the end.

Write for our catalogue.

Cuts Down Coal Consumption and Improves the Efficiency of Labor

THE COPES
Boiler Feed Regulator

is absolutely safe and reliable. It is the most simple, sturdy and rugged in construction. No ordinary regulator is so direct and positive in action.

As one prominent chief engineer says, "I selected the Copes because it is simple and rugged—everything is on the outside, and our tests substantiated every claim made for the regulator."

A straight tube, a lever, a heavy iron base, a practically frictionless balanced valve—that's all there is to it, as you will see in the illustration.

Designed on correct principles, there are no complicated, sensitive contrivances of uncertain reliabilty, nor weak, delicate parts subject to wear and likely to go wrong at the critical moment.

Once installed, out into service and adjusted by the user, further attention is seldom required by the Copes, and the first cost is usually the only cost, no further outlays or maintenance expense being called for.

Its operation is not affected by steam pressure, drafts, or climatic changes. The rate of feed is varied to insure the highest economy in steam making, where furnace conditions are bound to lag behind extremely irregular and unexpected fluctuations in boiler load.

Copes Boiler Feed Regulators are now made in Canada for Canadian power plants.

WEIR PUMPS

Delivery and Interchangeability

Any possibility of stoppage in the boiler plant is a serious matter. When, therefore, a new feed pump is required, prompt delivery is usually of the greatest importance.

As we always have a large number of our standard pumps in stock and in the course of construction, we are in a specially favorable position to meet demands for urgent delivery.

Overhauling and renewal is greatly facilitated by our system of interchangeable parts and the fact that we keep in stock at all times parts for our standard pumps.

Special attention is paid to the prompt dispatch of goods and the routing and shipment of all consignments. Special instructions in this regard always receive our most careful attention.

Prompt and careful shipment is but a single phase of Weir Service. To serve our customers in every way to the best of our ability is our aim.

LUNKENHEIMER

OIL AND GREASE CUPS

For Engine AND Transmission Bearings

By their unfailing reliability have won the reputation they enjoy. The engineer specifying "Lunkenheimer," **knows** that bearings thus equipped will get the amount of lubricant for which the feed is set; and that no further attention is necessary other than filling.

They are practical and durable; the feed regulation is simple and easily adjusted, and there is no danger of unsetting the feed when refilling.

The variety of types made embraces **Oil Cups** with Glass or Bronze Body, with or without Sightfeed; and **Grease Cups** of Bronze, Iron and Steel, with Screw or Spring Compression feed,—a type for every service requirement.

Write "Lunkenheimer-equipped" in your engine and transmission specifications, and insist on having the genuine.

Descriptive Booklets Nos. 523 and 524 D.C. will assist you in selecting the proper types. Write for copies.

TEMPERATURE INSTRUMENTS
Have Long Been the Standard for Scientific Accuracy and Precision
It is the faithful performance of the exacting duties of power plants that has established the prestige of Tycos Instruments. Their reputation rests upon the knowledge that there is a Tycos Instrument for every temperature problem in the boiler or engine room.
Temperature needs are summarized in a concise and convincing manner in Tycos catalogs. Send for them.

Use Starrett Hack Saws
Starrett Service goes with every box of Starrett Blades.
It begins with the fine quality of the saws themselves, and it's yours every minute of the day—any time you need it. Begin using Starrett Service now, and let Starrett Blades, backed by the Starrett Hack Saw Chart, show you why they're called "the blades that cut quicker and last longer."
Write for "Hack Saws and Their Use," the guide-book to more efficient cutting.

HOMESTEAD
Quarter-Turn Valves

A Homestead Was Chosen!

When one of the largest stoker manufacturers ran a competitive test for a valve which would give satisfaction under the severe service encountered in connection with their stokers, a HOMESTEAD was chosen.

This firm has since backed up its experience by standardizing on HOMESTEADS.

There is but one way of convincing yourself, give them a trial.

Homestead Valves are made in straight-way, three-way and four-way patterns.

Our Catalog is Yours for the Asking.

HOMESTEAD VALVE MFG. CO.
HOMESTEAD, PA.

Mr. Engineer, are you—

one of those wide-awake, up-to-the-minute engineers who is willing to be shown how economies can be effected in the boiler room? Many power plants in Canada and the United States, especially noted for high operating efficiency, consider "Bailey" meters essential to the best operation of either coal or oil-fired furnaces.

Bailey Boiler Meters

"Bailey" Boiler Meters — the **coal savers**—record the true relation between the coal and air supply to the furnace and plainly show the men what adjustments to either are required to maintain high operating efficiency and economy.

CHARTS SHOW PERFORMANCE OF INDIVIDUAL BOILERS

and tell when a boiler requires cleaning or inspection for leaky tubes or broken baffles. You can check the work of the fireman at all times.

Try one "Bailey" Boiler Meter and you will soon order "Bailey" equipment for all of your boilers.

May we send full details? Tell us your requirements.

MADE IN CANADA

An Ideal Attained By
ELESCO SUPERHEATERS

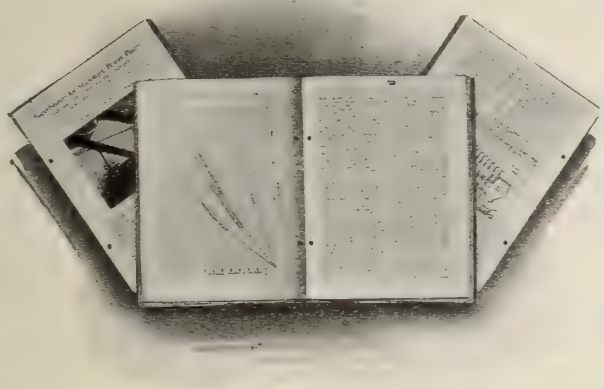
The Correct Application and Use of Superheated Steam

Superheating is too vital a factor in power plant design to be treated in any other way than as an engineering problem.

In the design and installation of Elesco Superheaters 26 different factors are involved. The success of Elesco installations is the result of the correct inter-relation of these factors.

Elesco engineers will study your conditions regardless of the size of your plant, and will co-operate with you in order that you may attain the one ideal toward which all discriminating power plant engineers are working — the economical, practical and reliable generation of power through the correct application and use of superheated steam.

An ideal is reached in plants equipped with Elesco Superheaters because guesswork has been avoided.



The Superheater Company
Limited
Transportation Building
MONTREAL

Works at Sherbrooke, Quebec

Send for Bulletin T-5

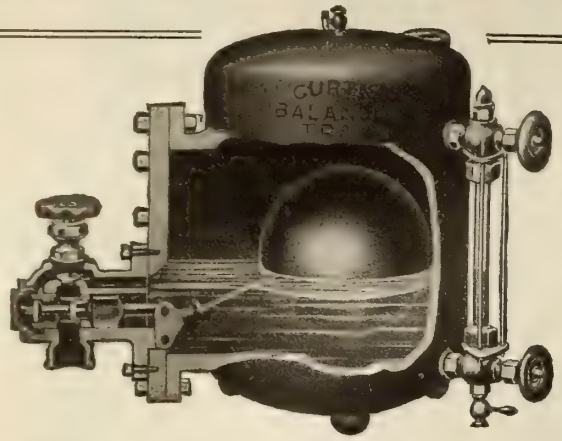
CURTIS Engineering Specialties



Five Superior Features of the Curtis Trap

1. A perfectly balanced valve.
2. An absolutely frictionless valve.
3. The valve can be removed without breaking a joint, starting a gasket, or taking out a bolt.
4. The valve being frictionless and balanced, the whole power of the float is available for opening and closing the valve.
5. Each trap will operate perfectly on pressure varying from one to 250 lbs.

Write for 1920 Catalog of Curtis Engineering Specialties.
Canadian funds are accepted at par at Montreal.

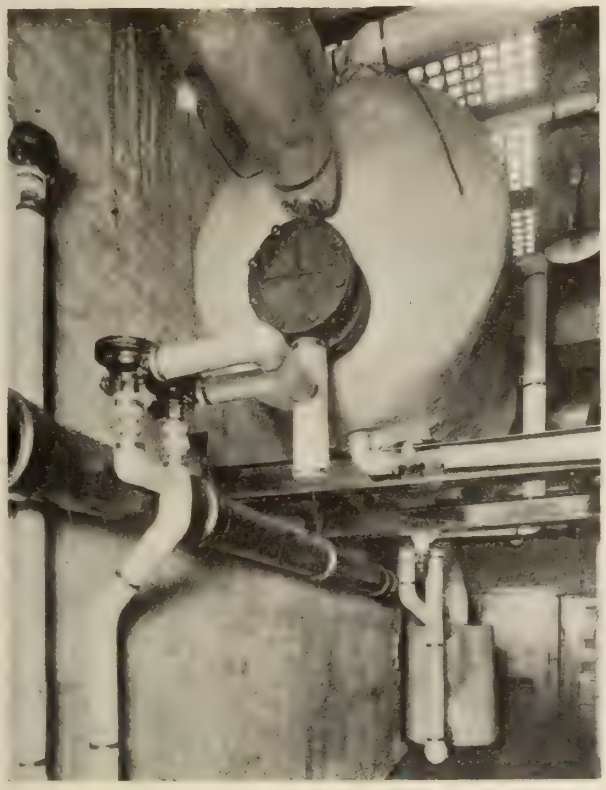
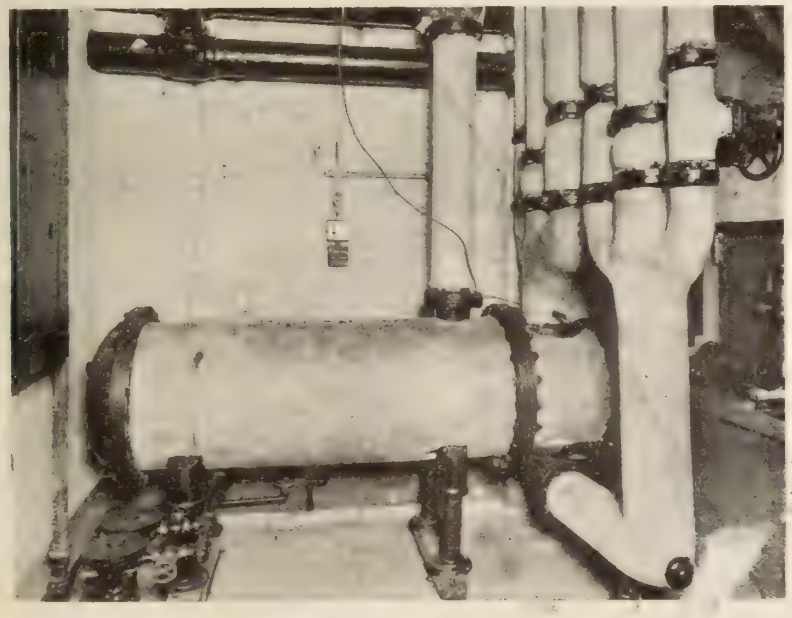
Sims Steam Tube Water Heaters



THERE are advanced features of design embodied in **Sims** heaters which distinguish them from other heaters—and **Sims** heaters are as superior in their service as they are different. **Sims** embodies straight tubes, 1½ in. O. D. Seamless Brass, rolled into a fixed head at one end, and a loose or floating head at the other. The tube structure is thus in no way attached to the heater. This construction admits of expansion and contraction of tubes without strain. Another feature is seen in the manner of grouping the tubes, which promotes the rapid circulation of water and allows for the best results in extracting the heat. **Sims** heaters have several other advantages. It is these advantages that have made **Sims** equipment preferred where large quantities of hot water, with live or exhaust steam as the heating water, are required.



The illustrations show Sims Water Heating Equipment at "Ardwold." Sir John Eaton's residence, Spadina Road, Toronto.

The upper illustration shows a 42 in. x 108 in. Sims No. 6 B.H. Clean E-Z Type Storage Heater for the Domestic Hot Water Supply. The lower illustration shows the Sims Converter, which supplies the swimming pool at "Ardwold."

For full information regarding Sims equipment write to—

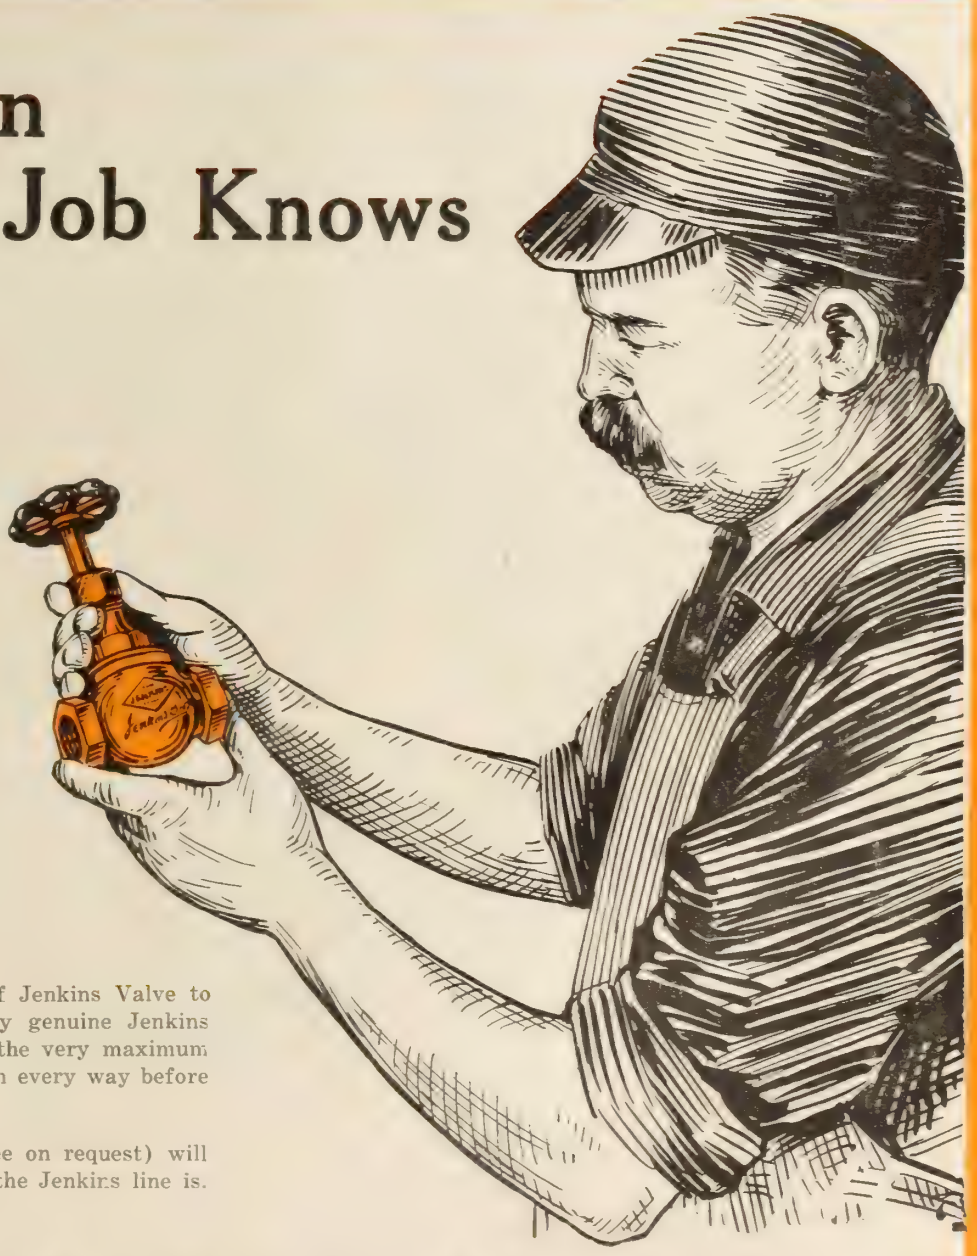
The Man On the Job Knows



It's his business to know Valves. He knows what they are called upon to do and that to be entirely satisfactory they must be so proportioned as to leave no weakness at any point.

He knows that the "Diamond Trade Mark" cast upon the body is a guarantee of the genuine

JENKINS VALVE

and that Jenkins Valves furnish satisfactory service year in and year out, even where the test of service is most severe.

There is a type and a size of Jenkins Valve to meet all requirements. Every genuine Jenkins Valve is designed to furnish the very maximum of service and is fully tested in every way before leaving the factory.

A copy of Catalog No. 8 (free on request) will show you how very complete the Jenkins line is. Write for it to-day.

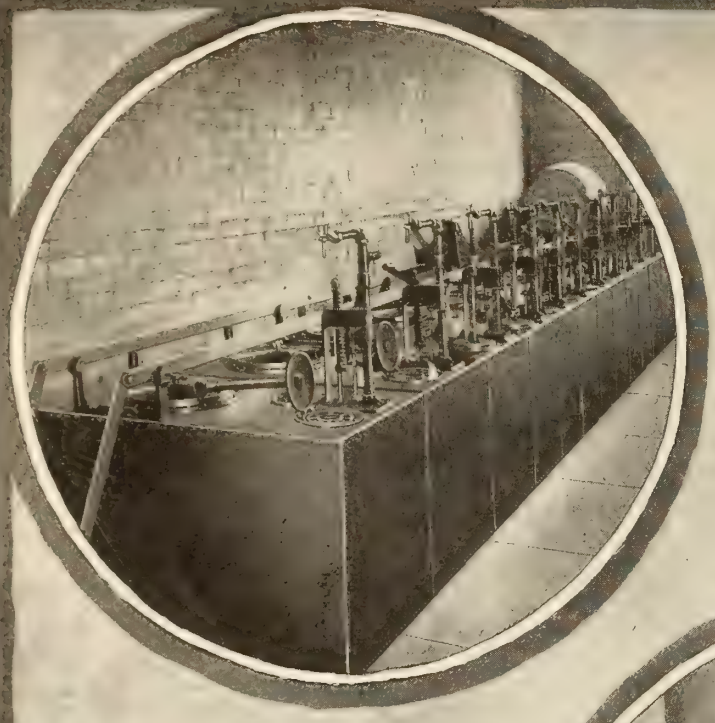
BOWSER

ESTABLISHED 1885



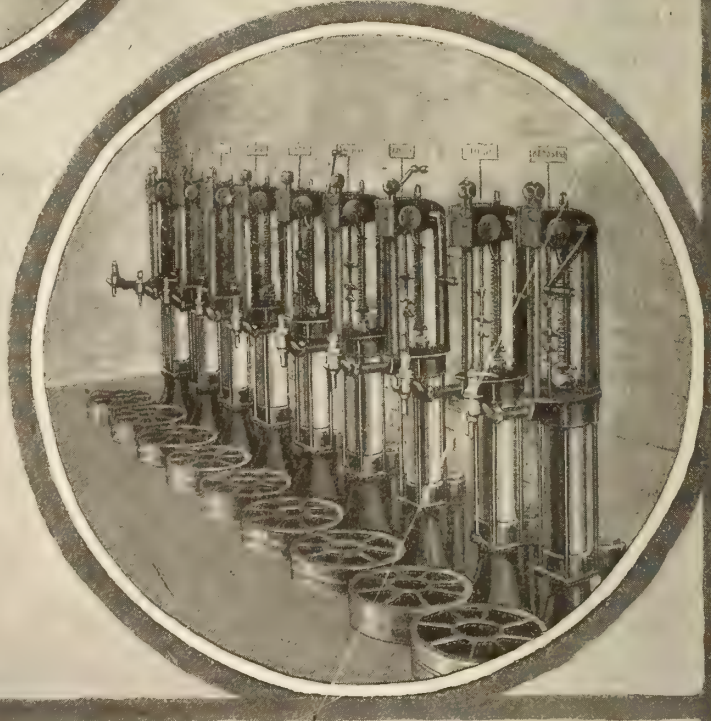
Savings Count Big!

With space at a premium, labor scarce and high, the price of oils way up, a

BOWSER
ESTABLISHED 1885
Oil Storage System

is a necessity that cannot be overlooked. Once its real value is understood, every one concerned in the handling of oils will want a Bowser System.

It saves an immense amount of oil and cuts labor cost. It is clean, safe and systematic.



Illustrations show two installations of Bowser Equipment used by the Lukens Steel Company, Coatesville, Pa.

Upper view shows battery of lubricating oil outfits with barrel, track and cradle.

Lower view shows battery of self-measuring pumps for paints and other non-lubricating liquids. These pumps are connected to a battery of tanks in another room.

Interesting literature will be sent on request.

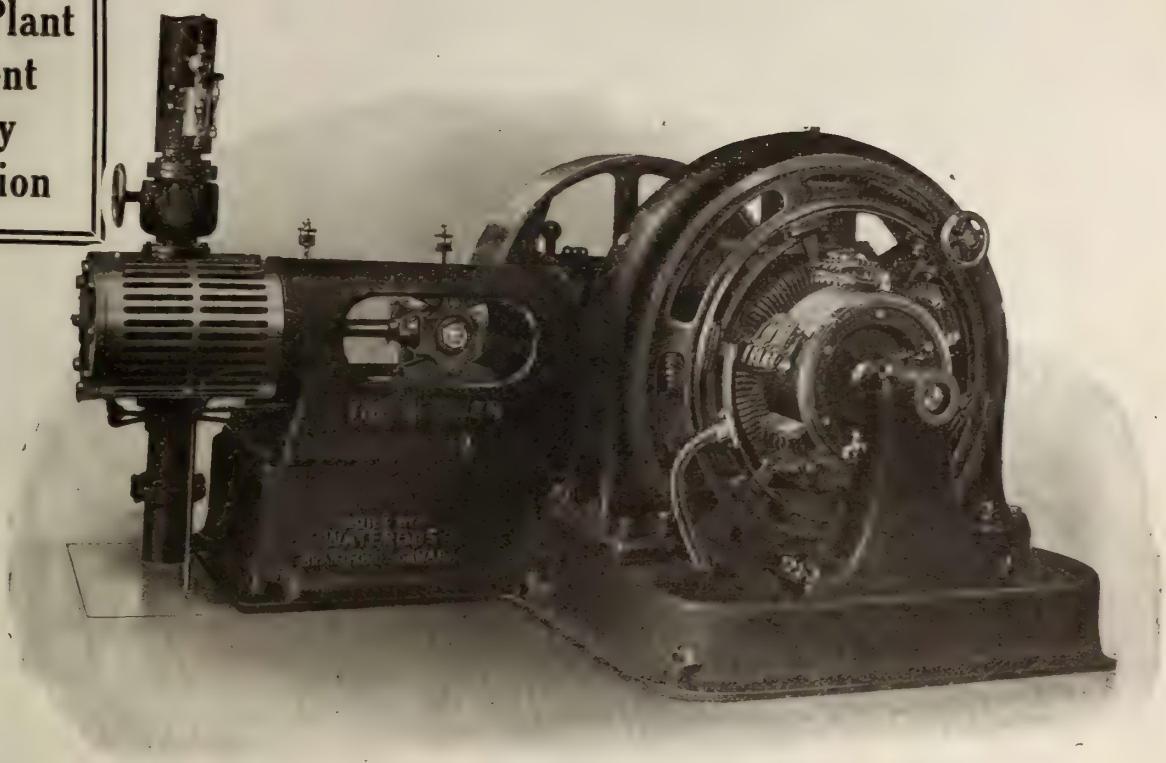
Toronto - - Canada

We Build Complete Power Plant Equipment for Every Installation



McEWEN HIGH-SPEED AUTOMATIC ENGINES

These dependable engines are built for continuous duty. They are your best insurance against costly repair bills and unexpected shut-downs.

They operate quietly and smoothly with an exceedingly close regulation under fluctuating loads. Sturdiness and their large reserve capacity enable them to respond instantly to heavy peak load demands.

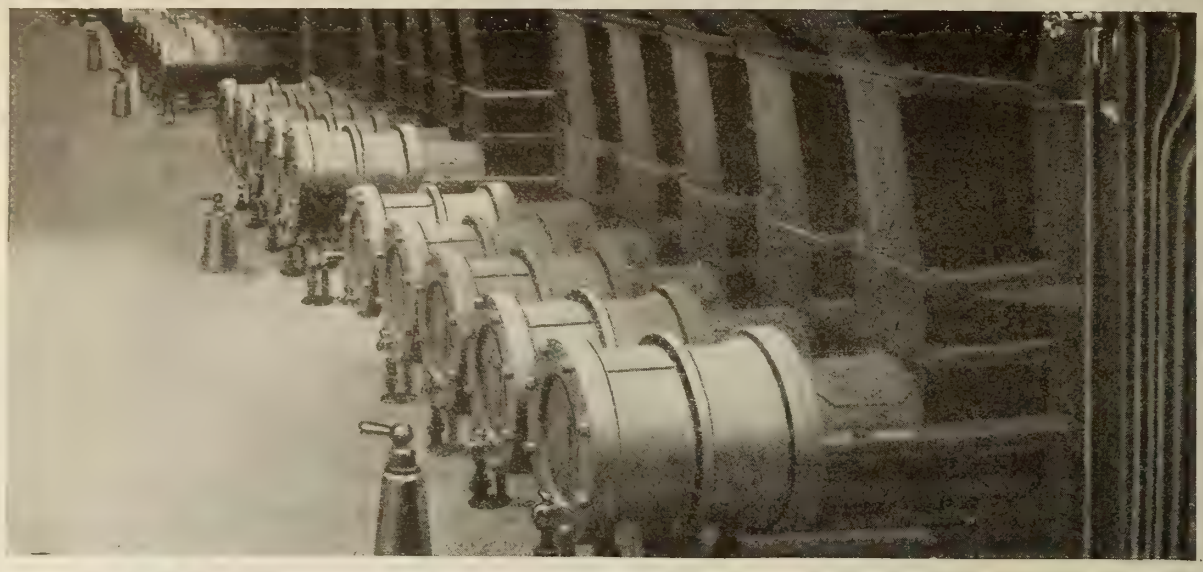
Your careful investigation of their actual service performance record in all parts of the country especially requested. Let us send you our list of McEwen users.

Built in simple and compound units up to 700 H.P. capacity. May we send you descriptive literature?

Waterous

BRANTFORD, ONTARIO, CANADA

POWER HOUSE, December 5, 1920. Vol. XIII., No. 23. Published semi-monthly at 143-153 University Ave., Toronto, Canada. Subscription price in Canada, $2; in United States, $2.50. Entered as second-class matter at the Post Office Department, Ottawa, Canada. Entered as second-class matter July 1, 1912, at the Post Office at Buffalo, under the Act of March 3rd, 1879.



High-Duty

—The Short Cut to Low Cost Power

HAVE you a definite conception of just what "high-duty" means as applied to the Jones "A-C" (Automatic-Cleaning) Stoker?

High-Duty Implies first of all, ability to meet any conceivable load condition, whether a steadily maintained overload or a widely fluctuating load where enormous peaks must be met almost momentarily. The automatic-control of fuel and air, and individual control of retorts embodied in the Jones "A-C," makes this a certain result.

High-Duty Means not merely heavy overload capacity, but ability to maintain overloads continuously without shutdowns and with minimum maintenance costs. The automatic-cleaning ("A-C") feature, the absence of clinker on side and bridge walls, and the rugged simplicity, making repairs almost negligible, insures *continuous operation at all loads.*

High-Duty Signifies not alone maintained overload capacity, but ability to fulfill this condition while burning every and any grade of fuel. The underfeed principle (a *Jones* principle) as perfected in the Jones "A-C," adapts this stoker to coals of every firing characteristic.

High-Duty Summarizes the features that have given the Jones "A-C" a wider range of utility recorded in greater return on stoker investment in plants of every size. The new "A-C" catalog goes into detail.

The services of an old-established and newly re-organized and expanded engineering organization — formerly the Jones Under-Feed Stoker Company, Limited, and now the Under-Feed Stoker Co. of Canada, Limited—are at your disposal. Request (without obligating yourself in any way) the new "A-C" catalog.

The Under-Feed Stoker Co. of Canada, Ltd., 81 Victoria St., Toronto

Jones "A-C"

Automatically-Cleaned *Automatically-Controlled*

How to Solve Your Bearing Problems

The cheapest and most reliable form of insurance against interrupted production from worn out bearings is to have on hand in your own shops several bars—in sizes to meet your needs—of

MUELLER
BRONZE BEARING METAL

These bars contain high percentages of copper and tin, giving a tough, close-grained casting to stand high speeds and heavy pressure. We carry a full assortment of Mueller Solid Bars from ½ in. O. D. to 4 in. O. D. in lengths of 12 ins.; in Mueller Cored Bars all sizes from 1 in. O. D. x ½ in. I. D. to 4 in. O. D. x 2¼ in. I. D.; all in lengths of 12 ins. Complete list of sizes and prices will be furnished on request. Mail orders given prompt attention.

Continuous service and low maintenance cost due to the self-cleansing seat

LUNKENHEIMER "DURO" BLOW-OFF VALVES

Remain tight under the most severe operating conditions because the self-cleansing seat feature eliminates the cause of most of the wear to which Blow-off Valves are subjected.

This self-cleansing seat feature,—exclusive in Lunkenhiemer "Duro" Blow-off Valves, functions automatically when the valves close by cutting off the inlet and allowing only a fine spray of water to pass, thereby removing foreign substances which may have lodged on the seat during the blow-off period.

In addition to the self-cleansing seat feature, the disc is reversible and has seat faces made of a durable alloy which readily accomodates itself to any irregularity in the seatring insuring tight though easily operated valves.

To further enhance their durability as a whole, all the parts are renewable.

Lunkenheimer "Duro" Blow-off Valves have proved their merit in service and are specified where boiler mountings of the better grade are desired.

All standard sizes, in material combinations to suit a wide range of pressure and temperature conditions.

Your local dealer can furnish them; if not, write us.

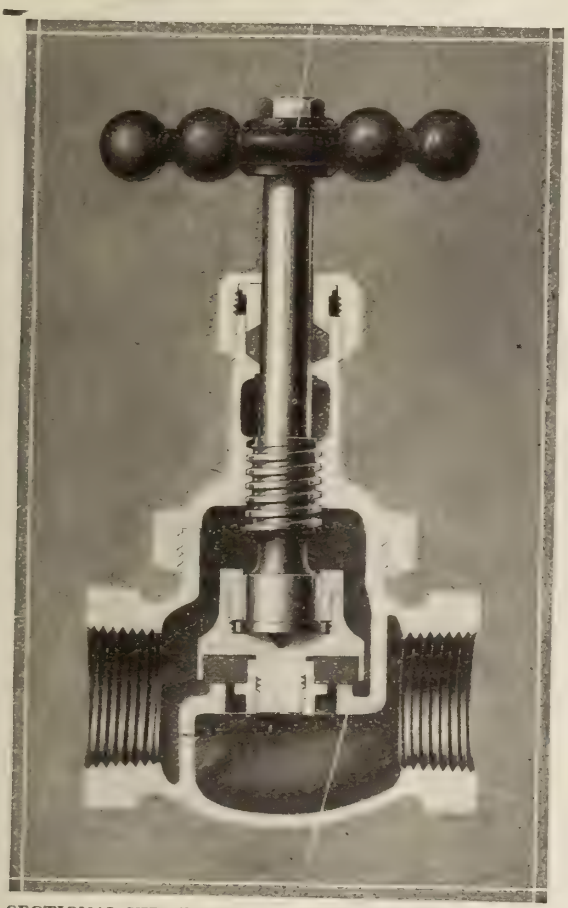
TRADE
PENBERTHY
MARK.

BE SURE THIS NAME is on the Valve you buy



SECTIONAL VIEW OF PENBERTHY COMPODISK VALVE
Registered and Approved for 175 lbs. Steam Pressure

Then you get "The valve with the outside bonnet construction."

The first progressive improvement made in brass valve construction in generations.

Think of the advantages! Valve always accessible.

No straining or stripping of threads when assembling or taking apart.

Impossible to spread or enlarge body of valve when screwing down bonnet to place.

No corrosion of threads, for they are on the outside, away from the action of steam and water.

Penberthy Valves Are High-Grade Valves

The fine quality of metal—the excellent workmanship and finish—the up-to-date design with the outside Bonnet Construction—the long wearing, serviceable Composition Discs—the Government approval of 175 lbs. Steam Pressure—all these advantages are yours when you buy the genuine Penberthy Valves. We also make the Regrinding Type approved for 200 lbs. Steam Pressure, as well as Brass Gates, Swing, Horizontal, Vertical and Angle Check Valves.

STOCKED BY LEADING JOBBERS AND MILL SUPPLY HOUSES IN CANADA

Depend upon *that Name*

The fallacy of too many packings

IF you've been using a certain special packing for this, that or the other job, you've probably a large assortment in the store-room and think of the waste! How much of that packing is good to use, right now? That's part of the price you have to pay for "too many packings."

PERHAPS you wonder how the same sheet can make and keep joints tight against superheated or saturated steam, air, ammonia and most chemical solutions. Yet Service Sheet Packing does this. It's a thin, strong, dense sheet of asbestos fibres, felted and bonded together with heat resisting compounds.

Then we come to rod and outside plunger packing.

Sea Rings, the automatic rod and plunger packing are designed to pack or press against the rod when there's pressure or tendency of leakage through the stuffing box, and release their pressure when the tendency of leakage diminishes. Power ordinarily wasted by excessive friction is saved, and the packing lasts much longer because of the reduced wear. Sea Rings cost more than the ordinary kind—they're worth more than they cost.

Piston Packing

Also there's a Johns-Manville packing that's built in folds—that won't fray out or unravel from constant wiping along cylinder liners like tucks or duck hydraulic. That's Universal Piston Packing—it's best for your pumps.

Kearsage Gaskets for boiler handholes and manholes. Vulcabeston Pump Valves for high or low pressure pumps. Mogul Valve Stem Packing for small rods and valve stems.

JOHNS-MANVILLE
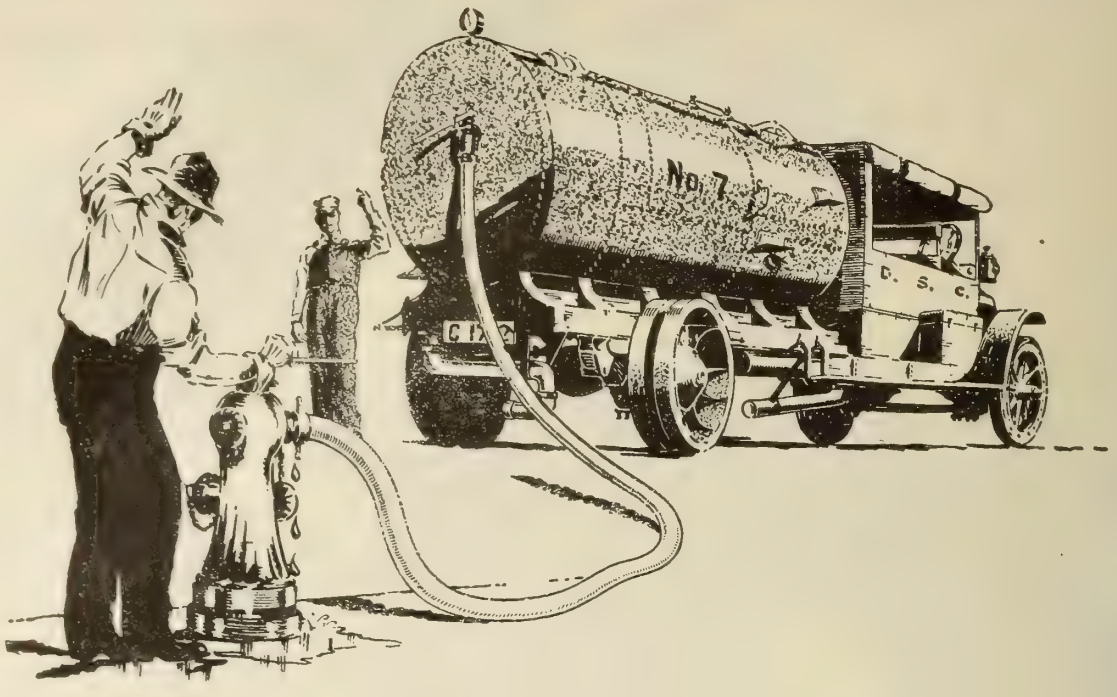
POWER PLANT MATERIALS



New Standards of Economy Set by Goodyear Industrial Hose

The outside covering on Water Hose, unless tough and sturdy, quickly disintegrates under the constant dragging over sharp objects, particularly in outside construction work. The hose blisters and bursts.

Goodyear has overcome this with a rubber cover of exceptional toughness and strength, a cover which gives longer life—at a correspondingly low cost. The good inner tube and strong fabric are in keeping with this superior cover.

For every industrial use—Water, Air Drill, Pneumatic Tool, Steam, Fire Hose—Goodyear has designed a *special* type of hose, built only after an exhaustive study of modern conditions in industrial work. Goodyear has broken new trails.

If your business is hampered by the excessive cost and unreliability of old-fashioned hose, get the Goodyear data and the Goodyear hose plan. Let a trained Goodyear man advise with you. No obligation on your part. Phone, wire, or write the nearest branch or Goodyear Mechanical Goods Service Station.

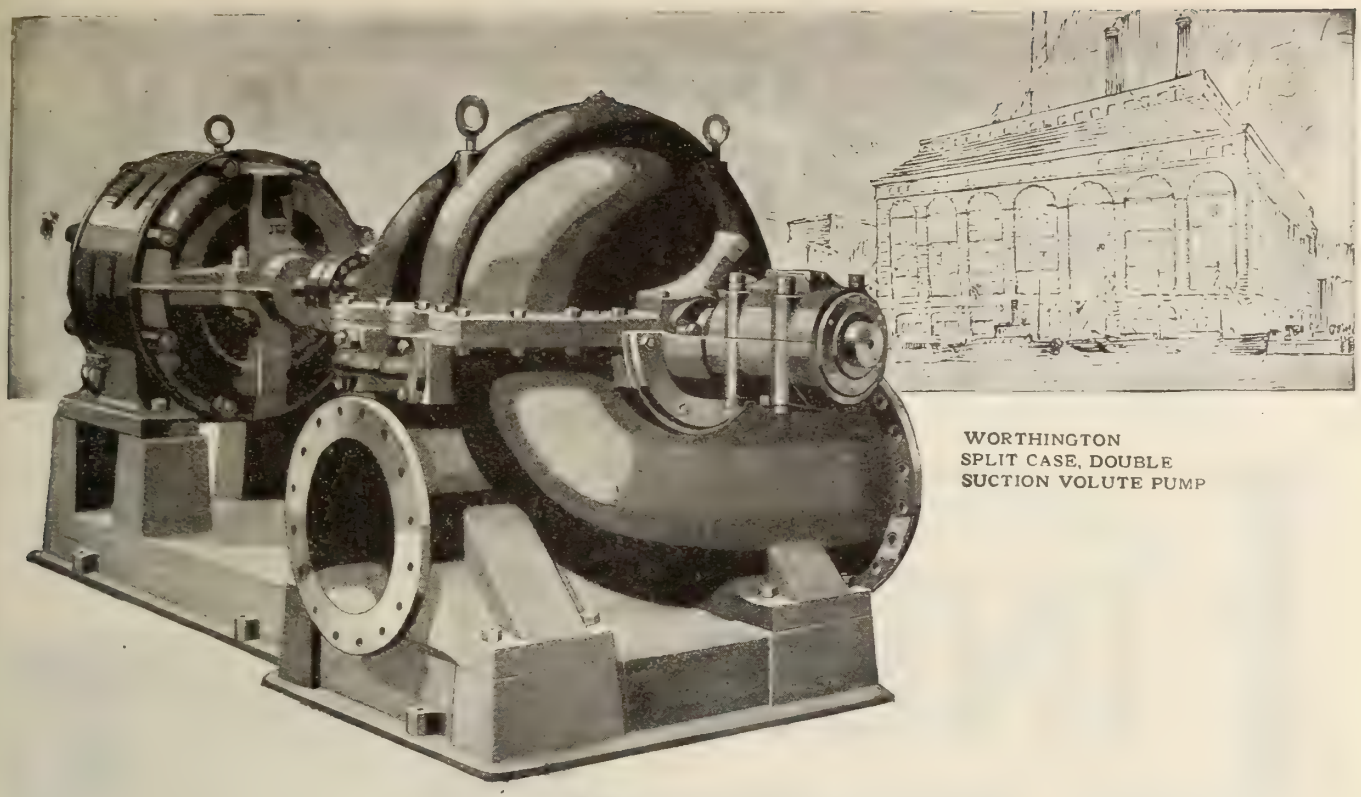
INDUSTRIAL HOSE



WORTHINGTON
SPLIT CASE, DOUBLE
SUCTION VOLUTE PUMP

This pump is made specially for you

FOR your opinions and findings have been carefully considered in the designing of Worthington Centrifugal Pumps. Your praises and plaints have been handed to our engineering committee by our men in the field. Constructive criticism has borne fruit.

Worthington Horizontal Double Suction Split Casing Volute Pump is the standard bearer of the Worthington line of centrifugal pumps. Our engineering committee has lavished a wealth of experience, knowledge and skill on this pump. And today it is serving successfully a wide range of industrial uses. For with minor construction changes, the original design becomes a special for special work.

Worthington Double Suction Volute Pumps fitted with special impellers or with other slight changes to suit your needs are guaranteed by Worthington to deliver efficient, economical pumping service.

LINDE

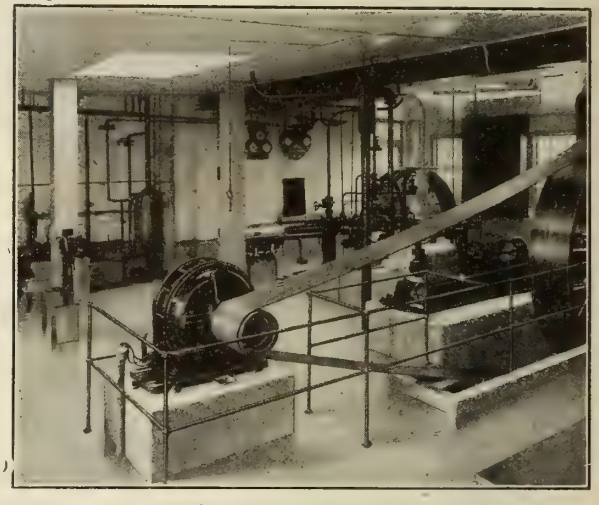
Made-in-Canada

Everything for Refrigerating or Ice Plants, Large or Small

Ice-making and Refrigerating Machinery

Twenty-four years of manufacturing prestige with a constantly increasing volume of business and a record of re-sales to satisfied owners are your guarantee of satisfaction when you adopt Linde equipment.

The new Linde Vertical Enclosed Type Machines embody the most up-to-date design and every modern convenience for small plants from 1 to 30 tons. Then for heavy demands, calling for loads up to 300 tons, our large horizontal frame type is unequalled. Write for full information.



This 100-ton plant was designed and constructed by our engineers. These men are at your service, designs, specifications and estimates on request.

is just as consistent as ice water covering on low temperature brine lines. You don't expect chill-room insulation to hold sharp freezer temperatures. Be just as reasonable about your cold pipe covering.

Nonpareil Cork Covering is made in three grades designed for three distinct service conditions:

Ice Water Covering, averaging 1½ inches thick, for refrigerated drinking water, liquid ammonia and other lines where the temperature is above 25° F.;

Standard Brine Covering, from 2 to 3 inches thick, varying with pipe size, for brine and gas suction lines with temperatures between 0° and 25° F.;

Special Thick Brine Covering, from 3 to 4 inches thick, for 0° F. and below, or where lines are exposed to unusually high surrounding temperatures.

Nonpareil Cork Covering, of the correct thickness and properly applied, is the most efficient, durable and economical insulation for cold pipes. For your protection the name, grade and size are stamped on each section.

A 64-page book, "Nonpareil Cork Covering," containing complete detailed information invaluable wherever refrigeration is used, will be mailed on request, free of charge, together with a sample of the covering.

Armstrong Cork & Insulation Company, 504 McGill Bldg., Toronto, Ont., Can.

Also manufacturers of Nonpareil Corkboard Insulation for cold storage and ice storage rooms; Nonpareil High Pressure Covering for steam lines, feed water heaters, boilers, etc.; Nonpareil Insulating Brick for boiler settings, furnaces, ovens, etc.; Nonpareil Cork Machinery Isolation for noisy machines; and Linotile and Armstrong's Cork Tile for floors in offices, residences, etc.

Nonpareil Cork Covering

QUALITY YORK SERVICE

York Uniflow Engines for Ice Making and Refrigerating Plants

One of the most important considerations in an Ice Making or Refrigerating Plant is the type of prime mover. An economical ice plant should have a dependable motive power, and one which will maintain a reasonable economy when called upon to operate over a range of from ¼ to 1¼ times the normal load.

It is well known among refrigerating engineers that the best compressor economy is obtained when evaporating pressures are carried as high, and condensing pressures as low, as possible. Even well balanced plants are forced to meet extreme seasonal conditions, with evaporating pressures varying from 20 to 30 pounds and condensing pressures from 85 to 225 pounds. These pressure variations and seasonal requirements of the Trade impose load factors of corresponding variation on the engine operating the compressor.

The Uniflow Steam Engine presents itself as the best solution of this difficulty

New Truths and Old Fallacies

Fusibility of Alloys—*Continued*

The best bearing metal may come to grief through mechanical defects, which no babbitt could withstand, or by reason of faulty lubrication, as a grease that is too heavy for a light-running bearing, or an oil too thin for a heavy bearing, will invariably cause heating.

A highly fusible alloy rarely, if ever, gives timely warning before running out, whereas a Magnolia-lined bearing heats so slowly that it permits of either shutting down or cooling off the bearing, while running, without injury to shaft or bearing, and we shall recite cases where entire lack of lubrication has done no harm.

Tin is not the only metal that lowers the melting point of an alloy.

It is most natural to suppose that the melting point of a lead-antimony mixture would not be lower than lead, but that the addition of antimony would even make it higher. The eutectic of this series is 87 per cent. lead and 13 per cent. antimony and the melting point is 447° Fahrenheit, or 212° Fahrenheit less than the mean of the two metals.

It is a common practice to guarantee the melting point of babbit metals to be 600° Fahrenheit, and over, and to view this practice from a charitable standpoint, this guarantee is doubtless given because it is taken for granted that such ought to be the melting point. It is quite evident that the guarantors are not hampered by facts and have no definite knowledge upon which to base their assertions, but they run no risk of detection as buyers are just as much in the dark.

We have a Die-Casting Catalogue of recent date in which is given the melting point of their Genuine Babbitt as 810° Fahrenheit. We believe these figures were obtained from a college laboratory, which gives absolution from intentional misrepresentation, as it is highly improbable that such a wonderful alloy exists, but like many other babbitt manufacturers, they don't know any better.

"I'm astonished to find that such an efficient stoker is so simple!"

That's what an experienced stoker man exclaimed after he had seen the Stowe Stoker in operation.

The Stowe Stoker is really simpler than the chain grate. Alternating tuyeres and chains—that's all there's to it. Drippage falls into a pit provided for that purpose, instead of clogging air passages. There are no air ducts in the firing aisle.

As compared to the chain grate, only *half* the grate surface of the Stowe Stoker actuates; and yet, it provides a graduated air supply for the various stages of combustion, and adapts itself to force draft with no more ado than is involved in the application of forced draft to a hand-fired grate. Furthermore, it positively discharges the refuse at a rate which can be controlled independently of the rate of feeding.

When one considers first, the many striking features and advantages of the Stowe Stoker, and then, the marked simplicity of this mechanism, the realization comes that here is a truly great *achievement* in mechanical equipment design.

We also manufacture the L-C Chain Grate Stoker—the Natural-Draft Type for Higher Volatile Coals—Dominant in this Field Today.

Burning Wet Tan Bark on Mechanical Stokers

Tan Bark, Carrying From 40% to 50% Moisture, is Burned With a Very Small Proportion of Coal—The Boiler Room is a Model of Good Arrangement.

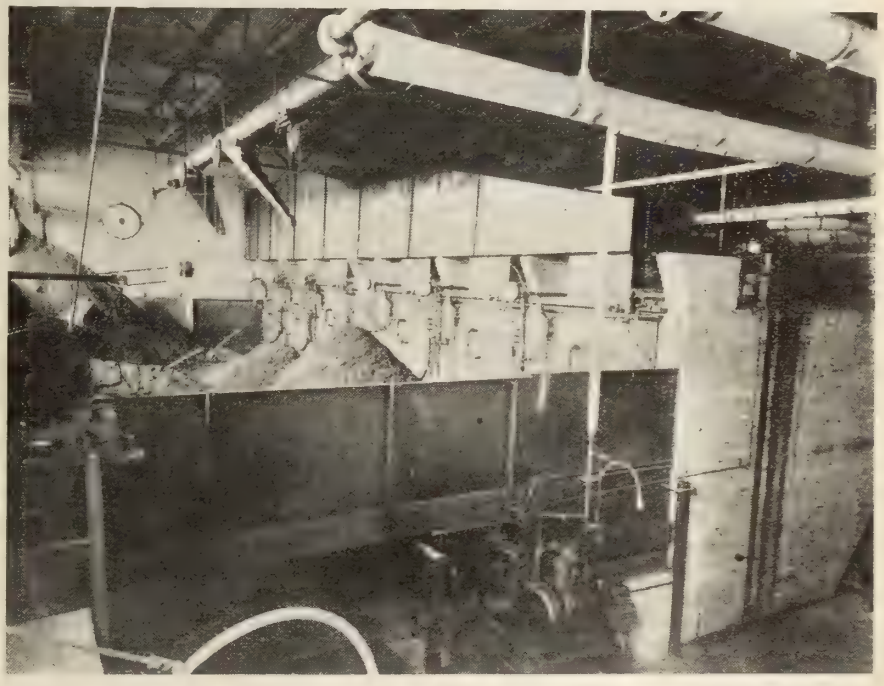
By T. H. FENNER

IT is a fortunate firm these days that can supply itself with power and heat for manufacturing purposes without the need of coal, or at least with a very small proportion of coal. Some special industries, notably those engaged in wood working processes, are able to use the refuse of manufacture to generate steam. The firm we have in mind at present is not in the woodworking business, but in that of tanning hides, and like the first named, have a lot of refuse which can be used for steam generation. This is known as tan bark, and possesses a certain heat value, though this is a very low one.

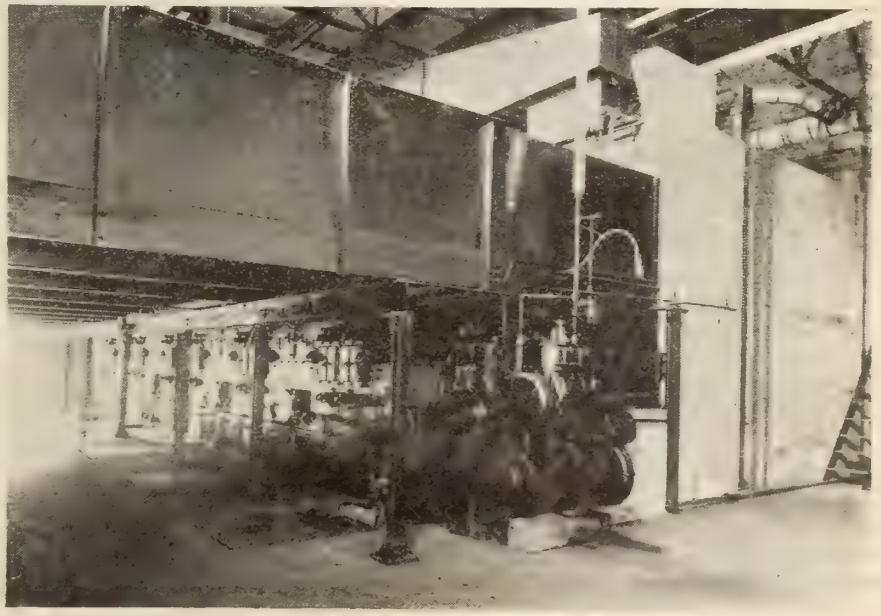
The burning of tan bark under boilers is complicated by the fact that it is very highly impregnated with moisture as it comes from the extractors. In small tanneries it is not unusual to use the bark with hand firing, but in these cases it is usually allowed to dry out. In the plant we are dealing with here, the bark goes to the furnace direct. The firm is the Lang Tanning Co., of Kitchener, Ont.

A Good Layout

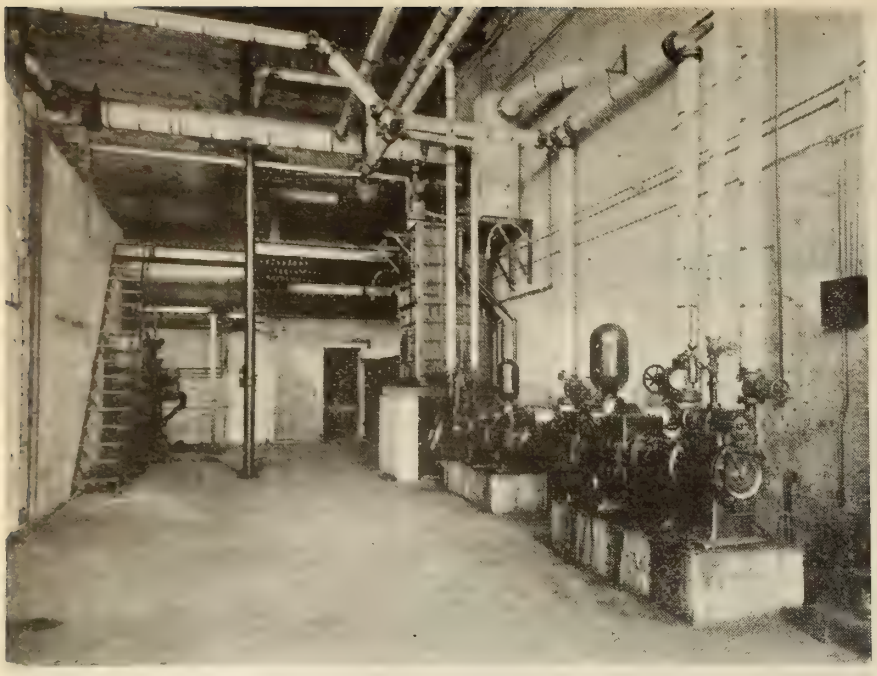
The general design of the boiler room was under the supervision of Mr. August Lang, and reflects a great deal of credit on that gentleman. It is notable for having plenty of space and very convenient arrangement. The boilers are six in number of the horizontal return tubular type, 72 inches diameter by 18 feet in length, built by Goldie & McCulloch Co., of Galt, Ont. They are equipped with mechanical stokers made by the Detroit Stoker Co., of Detroit, Michigan. The power plant consists of a 250 H.P. Corliss engine, made by Goldie & McCulloch, which, by the way, was the first Corliss engine made by this firm. It is sixteen years old, and the writer was informed by Mr. Lang that it had never cost a cent for repairs since its installation. This speaks well for both builders and operators. The feed pumps are of the outside packed horizontal type, by the same makers, and the feed water goes through an open heater before reaching the pumps. This is also made by the Galt firm. The exhaust steam from engines and pumps is used



TOP OF HOPPERS. SHOWING PILE OF TAN BARK. AND CONVEYOR ABOVE.



STOKER FRONTS AND OPERATING MECHANISM. HOPPER ABOVE.



FEED PUMPS AND DISTRIBUTING VALVE PLATFORM.

in the heater and for factory purposes, while a considerable amount of live steam is also used in the factory. The steam piping and feed water piping have been laid out with a view to making things handy for the man on the job. The top of the stokers forms a working platform in front of the boilers, and the boilers are set in two batteries of three each. In the space between is placed an iron stair and platform, leading down to the stoker floor. On the side of the boilers, in the passageway, are placed the feed valves, three on each side for the corresponding boilers. In this way the man in charge can adjust every valve at one time, without the necessity of walking from boiler to boiler. He can see plainly every gauge glass from his position on the platform, and as his eye is level with the glasses, observing the water level is easy. This is perhaps a simple detail, but this arrangement of valves saves an enormous amount of walking about during the day.

The steam pipe is anchored at one end, and connected to each boiler through suitable bends. It is laid on supports, with rollers between the pipe and support, to allow perfect ease of expansion. At the end of the boilers, there is another ladder leading from the ground floor to a platform level with the boiler tops, and over this platform, at a convenient height for a man to reach, are placed the distributing valves to the engine and all the steam lines in the factory. This again is a most convenient arrangement. The space at the back of the boilers for cleaning purposes is ample, and the blow-off pipes from each boiler are connected to a main trench which leads away to the sewer. Each boiler is equipped with a circulating and surface blow-off arrangement.

A certain amount of coal is used in conjunction with the bark, and this is supplied to the stokers from an overhead bunker. The coal storage is outside the building, and the coal is elevated to the bunker by a drag conveyor, whence it flows to the hoppers. The tan bark is brought from the factory to the hoppers by a scraper conveyor, and dumped in a pile as shown in the photo. A certain amount of trimming is necessary, but one man can comfortably look after the whole of the firing, water tending, etc.

The heat value of the tan bark is said to be in the neighborhood of 600 B.T.U. per pound at the amount of moisture carried, which is in the neighborhood of 50 per cent. According to Mr. Lang, who has had many years' experience in this line, great difficulty has always been experienced in burning it successfully. Dutch ovens have been tried with but indifferent results, but the present arrangement is the most successful yet tried. To get the necessary draught a 250-foot chimney is used. The plant has been installed but a short time, and thorough scientific tests have not been made, but we understand that these will be available in the near future. We hope then to be able to present them to our readers.

AN ECONOMISER EXPLOSION

The Board of Trade report on an economiser explosion, which occurred in Huddersfield, emphasises the necessity for handling these valuable adjuncts to boiler plants properly if accidents are to be avoided. The economiser in question was evidently in good condition and quite capable of withstanding ordinary reasonable service, but it exploded one morning and wrecked all the adjacent brickwork. Had the accident happened a few minutes earlier, when the mill hands were passing by on their way to work, there would probably have been many fatalities. As it was, no one was even injured.

The economiser was used to heat the feed water for three Lancashire boilers, and the flues were so arrangd that the gases could be by-passed direct to the chimney. The mill engine, which was supplied by the boilers, was ordinarily run from 7 a.m. to 5.30 p.m., and then shut down for the night, when the fires were banked and left in charge of the night watchman. Feed water for the boilers was supplied by a ram pump belt-driven from the main engine, or by an injector. The ram pump started and stopped with the engine. During the night the watchman occasionally fed a little water into the boilers, through the economiser, and would naturally have to use the injector for the purpose. In the early morning he began to raise a full head of steam, and to get the necessary draught opened the dampers to pass the gases through the economiser. At 7 o'clock the engine was started, and very shortly afterwards the economiser burst.

It is fairly evident that the cause of the accident was a sudden change in the temperature of the economiser tubes. During the hour and a half while the steam pressure was being raised, but no demand made on the boilers, the economiser would get very hot. When the engine was started the feed pump drove the cold feed water into the economiser. The sudden contraction of the tubes, caused by the cooling, cracked them and they blew up under the steam pressure. The proper way to handle the plant would, of course, have been not to pass the hot gases from the fires through the economiser until feed water was needed by the boilers, and it might even be necessary, on account of leaky dampers, to keep down the temperature of the economiser during the night by giving it a little feed water. Added to these considerations, it would be better, for the sake of economy in coal and for the prevention of external corrosion of the economiser tubes, if the feed water were warmed before being led to the economiser in the ordinary course of working.—The Engineer.

Note.—Feed water should never enter an economiser at less than 90°, and preferably higher.—Editor, Power House.

The Worthington Pump and Machinery Corporation have issued a very complete and well illustrated catalogue of their marine pumping equipment. This covers horizontal, vertical and centrifugal pumps for boiler fuel, ballast and circulating purposes. Cross sectional views are given showing the details of construction of some types of pumps. While primarily a marine catalogue, many of the pumps illustrated are equally suitable for stationary purposes.

Regarding the Control of Combustion

By T. A. PEEBLES

THE losses occurring in the generation of steam are usually divided into two groups, one of which is necessary and the other avoidable. In considering the necessary losses it is assumed that a perfect stoker will burn all the fuel with the theoretical air supply, there being no loss due to excess air, incomplete combustion, or combustion in the ash, and the boiler is assumed to be theoretically capable of cooling the gases to the temperature of the water in the boiler.

Necessary Losses

The heat required to raise the temperature of the dry chimney gases from atmospheric temperature to that of the water in the boiler, and the amount expended in evaporating the moisture in the fuel and air, and that formed by the burning of hydrogen, are assumed to be necessary losses.

In the modern central station each boiler is equipped with an economizer and if the steam-generating unit be considered as consisting of stoker, boiler and economizer, this division of the losses is no longer acceptable. If certain difficulties which are encountered when cold water is supplied to the economizer were overcome, water could be pumped from the condenser direct to the economizer and the so-called necessary losses eliminated. Such a unit will absorb 85 per cent. of the total heat of the coal. (Recent tests in Europe have shown test efficiencies of over 88 per cent.)

It will usually be found that a plant which has boiler and stoker equipment capable of giving an overall officiency of 85 per cent. has the very best steam turbines available and they will approach 80 per cent. Rankine cycle efficiency. In the high grade plants, therefore, the boiler room can approach more closely the theoretical maximum than can be done in the turbine room. Smaller plants, having probably somewhat less efficient steam generating equipment will also have less efficient steam consuming equipment and again the economy in the boiler room, under proper conditions, will exceed the economy of the turbine room. The same is true of the small plants using hand-fired H.R.T. boilers and reciprocating engines.

The Why of Boiler Room Improvements

Why is it then that the statement is so often made that improvements in power plant economy must be made in the boiler room? Simply because the performance of a turbine is determined by the design, and being largely independent of the operation, results secured in service closely approximate the best test results, while, unfortunately, a very different situation exists in the boiler plant, where constant attention is necessary to the attainment of results approximating test conditions. This is exactly why the boiler room fails to give satisfactory results in regular operation. The difference cannot be ascribed to dirty heating surfaces, because where surface condensers are used or where the water is properly treated, the inside of the heating surface is kept clean, and with a good installation of soot blowers, properly operated, the outside of the heating surface is also kept practically clean. The loss comes in the improper control of the fuel and air supply and it is here that improvement must be made if test results are to be approximated in daily operation. While certain plants are doing this successfully, it requires an organization such as only a few plants have been able to develop.

Regulation by Automatics

Many attempts have been made to control the fuel and air supply automatically, but they have been only partially successful, largely because this problem has not been given the study which its importance clearly demands. These automatic regulators all work from variation in steam pressure, and before they will respond there must be a change in the one factor which should remain as nearly constant as possible. There is always a lag between a change in steam demand and the resultant drop in pressure, requiring that an over adjustment be made in every case to meet, not only the changed demand, but also to make up for the lowered pressure which must occur to actuate the regulator and bring about the necessary correction. This over adjustment, therefore, causes a variation in steam pressure, the reverse of that which originally produced the adjustment and a tendency to "hunt" is thereby established. A boiler so controlled will always be operating at a higher or lower rating than the actual demand at that particular time. Well managed boiler plants operate with the right number of boilers in service, so that the plant load will be carried with boilers operating it, at or near, their most efficient point. It therefore follows that any operation above or below this particular rating will be at an efficiency below the maximum which can be secured. The regulating apparatus usually employed will not move incrementally with variations in steam pressure, but tends to make a complete movement to either a closed or open position for each increase or decrease in pressure of sufficient amount to operate the regulator. This still further aggravates the tendency of the regulating mechanism to "hunt" and the net result is a period of operation at a minimum rating, for which the fuel and air supply are adjusted, followed by an interval of operation at maximum rating. Such conditions cause wide variations in furnace temperature with the attendant troubles from furnace brickwork and boiler parts which invariably result from such operation.

Where steam engines or turbines are used for driving stokers or forced draft fans, the regulator is employed to operate a balanced valve located in the steam line to such units. These balanced valves have a relatively short travel between minimum and maximum opening, and when operated by a regulator which has a tendency to "hunt," impose very severe service on the steam-driven unit, operating it intermittently, at maximum and minimum rate with sudden changes from one extreme to the other. The same condition exists where the rheostat of a motor-driven unit is controlled by such a regulator.

The fuel bed resistance depends upon the condition of the fire and the rate of combustion, and it is disastrous from the standpoint of economy to double the draft and the fuel feed just because the steam pressure has dropped slightly, or reduce the draft to a minimum for a slight increase in pressure. The maximum and minimum ratings are both points of low efficiency and this condition is aggravated if the draft is varied from one extreme to the other so suddenly that there is no corresponding change in the thickness of the fuel bed.

Going Back to Hand Regulating

The boiler plant superintendents, who have made a careful study of the control of combustion, have usually abandoned this type of automatic in favor of hand regulation, with the assistance of certain indicating and recording instruments. The damper operating levers, and the fan and stoker controlling devices are located at a convenient point with steam flow meters and draft gauges so mounted that the fireman can observe from these instruments the effect of each adjustment made. By observing the flow meter, the fireman is able to determine the demand on the boiler and by means of a large pilot gauge he is informed immediately of any change in steam pressure, and is therefore able to make the necessary adjustments to meet the demand for steam and maintain a practically uniform pressure.

Draft gauges and gas analysis instru-

ments enable him to determine whether or not the relation of air supply to fuel supply is being maintained correctly. With this equipment at his command, the intelligent fireman can secure results which closely approximate test efficiencies, but the difficulty of building up and maintaining an organization capable of doing this is demonstrated by the small number of plants which are actually securing such results in daily operation. It is, therefore, important that automatic apparatus be developed which will actually make the necessary adjustment to maintain correct conditions.

What a Successful Regulator Must Do

Just as the skillful fireman depends, first, on the indications of the flow meter, and, second, on the pilot gauge, a successful automatic regulating mechanism must respond primarily to variations in the rate of flow of steam with secondary control from variations in pressure. The fireman makes adjustment of fuel and air supply in proportion to the change in the flow meter reading or the indication of the pressure gauge, making only slight adjustment for a slight change, and greater adjustments for the wider variations. The automatic regulating apparatus must do exactly the same thing, and must not under any circumstances go from one extreme position to the other extreme, unless a very exceptional condition of load required it. Where stokers or stoker auxiliaries are steam driven, the steam supply must be controlled by means of the automatic regulator, through the medium of a regulating valve, which can be readily adjusted for the correct amount of steam, corresponding to any given demand on the boiler and which will give finely graduated control between the two extreme positions.

Where forced draft is employed, the careful fireman reduces the draft before cleaning fires. The regulator must be so arranged that the draft can be momentarily adjusted without disconnecting the regulator from the dampers or controlled valves which it is operating, and it must remain in the desired position irrespective of changes in steam flow or steam pressure, until the cleaning period has been completed. When the soot blowers are being operated, the boiler damper should be wide open, and the automatic regulator should be so arranged that the boiler dampers can be put in a wide open position and held there, irrespective of changes in steam flow or pressure, until the soot blowing has been completed.

Mechanically, the apparatus must be rugged, and substantial in design and construction. It must be sensitive to slight variations in flow of pressure, and the vital parts must be so protected that the regulator can operate under conditions found in the ordinary boiler plant without frequent overhauling and repair.—Combustion.

Explosion of an Oxygen Tank

THE accompanying engravings show some of the damage done recently by the explosion of an oxygen tank. One man was killed, a considerable number of persons were more or less seriously injured, and the property loss was large.

The tank, which was used for storing electrolytic oxygen, was about ten feet long and four feet in diameter. The shell was made of 7/16-inch plate, laid in two courses, each five feet long, and the longitudinal (or "fore-and-aft") joints were of the triple-riveted lap type, having a calculated efficiency of about 75 per cent. The upper head of the tank was convex, and the lower head was originally concave. (This method of construction is not altogether ideal, but it is reasonably safe for ordinary purposes, when a factor of safety of at least five is used by the designer.) A safety-valve was provided and adjusted to blow off at 100 pounds pressure.

The initial rupture apparently occurred in the solid plate, the line of fracture running parallel to the length of the tank, but keeping well away from the riveted joint. The shell tore away from the head at one end, and the line of rupture also followed the girth joint at the middle of the tank, so that a considerable part of one of the sheets opened out like a leaf in a book or magazine. (See Fig. 1.) In addition to this, the lower head, which was originally concave, was ruptured along one of its diameters, and its curvature was reversed so that it was convex after the accident.

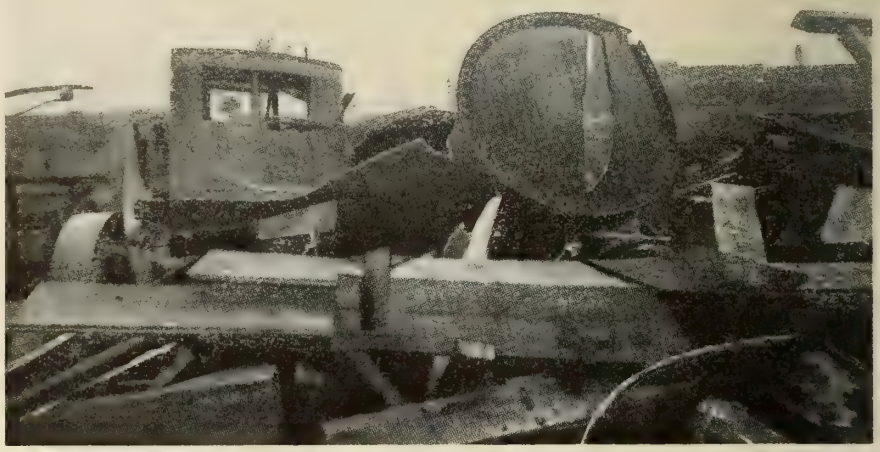


FIG. 1—EXPLODED TANK AND RUPTURED HEAD.

FIG. 2—GENERAL VIEW OF THE RUINS.

The cause of the explosion is not definitely known. In connection with the

FIG. 3—GENERAL VIEW OF RUINS.

production of electrolytic oxygen there is always a possibility of reversal of polarity occurring in the electric generator, and a consequent mixing of oxygen and hydrogen; but it is believed that this did not occur in the present case. It is far more probable, in our opinion, that the accident was due to the presence of lubricating oil in the tank. Pumps used for compressing oxygen are supposed to be lubricated with soap, or merely with water; but it is said that distinct traces of lubricating oil were found on the lower head of this tank after the explosion. The use of any true oil for lubricating purposes in connection with the compression of oxygen is always dangerous, and it appears to be highly probable (as we have already said) that this accident was due to the presence of such oil, and to its spontaneous explosive combustion. It also appears to be more than doubtful if the gas was properly tested for purity.

The exploded tank was supposed to be strong enough to require a pressure of 1,000 pounds per square inch to produce rupture,—assuming that the pressure was applied steadily and with gradually increasing intensity. In accordance with well-known mechanical principles, however, a suddenly-applied pressure of materially less magnitude might produce failure. We have no way of knowing what the actual maximum pressure may have been.

This accident, whatever its cause may have been, illustrates the reality and seriousness of the danger associated with the handling of compressed gases, and demonstrates the need of exercising great care to keep every kind of combustible matter away from compressed oxygen,—whether the combustible material be gaseous, liquid or solid.—Travellers' Standard.

MICA AND ITS USES

Mica is one of the most useful minerals, the production and distribution of which is little known. Of the many varieties, only three are of commercial importance, and of these but two are available in any quantity—the muscovite, or white mica, and the phlogopite, an amber mica. The latter is the most important of Canadian micas.

India is the largest producer of mica, providing over 50 per cent. of the world's supply. Canada produces about 25 per cent., and the United States and other countries the remainder.

In Canada, mica occurs pretty generally. The most productive areas are situated along the lower St. Lawrence below Quebec, north of the Ottawa near Mattawa, and in the townships of Burgess in Leeds county, Lanark in Lanark county, and Loughborough in Frontenac county, also in a few areas in British Columbia. The production of 1919 was valued at $273,305.

Mica mining is attended with many difficulties. For successful exploitation it is essential that the miners be experienced in the mining of this material, and be familiar with the special conditions and problems it presents. Many good mica deposits have been abandoned on account of the lack of experience of the operators.

The general run of mine mica is of a small size. A very small percentage produces sheets of 4 x 6-inch surface, while fully 50 per cent. will cut to 1 x 3 inch sheets only. Fortunately, a process of cementing the small sheets enables the building up of larger surfaces. This product is known as "micanite" or "mica board" and is mostly used in the electrical industry for insulation. Mica is largely used in the manufacture of boiler and steam pipe covering, its insulating properties exceeding by far that of any other known substance. Comparative tests have demonstrated that the loss of heat from bare pipes has been reduced by 90 per cent. when the pipes were enclosed in mica covering.

Owing to its resistance to shock, mica is used for spectacles or goggles worn by workmen in industries where flying chips or sparks endanger the eyes, and in observing processes of melting and fusing in furnaces. The small pieces of mica, formerly wasted, are now used for various purposes. When ground fine in oil, mica forms a valuable lubricant, especially for shafting or journal boxes on locomotives or railway cars. Ground mica, when mixed with a flux, is also used in giving to wallpaper and other substances a silvery effect.

So many uses are being found for mica that what was formerly an industry with a very large proportion of waste is now one in which the material is almost completely utilized.

LONDON LODGE NO. 30 C.A.S.E.

The regular meeting of the C.A.S.E. London No 30, was held on November 19, and took the form of a social evening. A splendid programme of reading and solos was greatly appreciated by all present. After the programme a dainty lunch was served by the Ladies' Auxiliary.

There were about fifty present and a splendid time was enjoyed by all.

Brother Noll, who acted as chairman, made a suggestion that the gentlemen take charge of the next social and provide entertainment and refreshments.

On Thursday December 2, Brother D. F. Campbell will give a lantern slide lecture at the Technical School on steam turbines.

THE MOST POWERFUL GAS ENGINE

This distinction is claimed for an engine made by the Cockerill Society in Liege, Belgium. In August, 1914, it was in process of erection. The Germans after the capture of the city allowed it to be put into operation and, when they were assured of its success, took it from its owners and sent it into Germany, to Duisburg, where it was running at the time of the Armistice. It was then sent back to Liege, where it was installed for the second time, with the addition of some improvements. It develops 8,000 h.p. The cylinders, four in number, are 1.3 m. in diameter, 1.5 m. stroke, 94 r.p.m. The heat of the gases coming from the engine is used to generate steam for a turbine.—La Nature.

High Priced Coal.—Notwithstanding a general decrease in the prices of foodstuffs, Windsor dealers increased the price of anthracite coal to $26 a ton, approximately $10 more than the price being charged in Detroit. The difference in exchange and a shortage of coal are responsible for the step, it was explained.

A Course of Instruction for the Graded Certificate

We Will in This Course Go Through the Mathematical and Theoretical Work to Cover Every Grade of Certificate Issued by the Ontario Board

By T. H. FENNER

THERE has been so much written and spoken on the subject of combustion of late years, that it should be written in letters of gold on the tablets of the engineer's memory. However, this is probably not the case, so we will go over this important subject briefly, not from the view of the theorist, but from a practical standpoint.

Fuel of any kind is merely the reservoir in which nature has stored up heat, some kinds of fuel carrying more heat units to the pound than others. Combustion is the act of liberating these units of heat and by mixing the various constituents of the fuel with a proper proportion of oxygen, ensuring the full benefit of these heat units being secured. It is on this mixture of air that efficiency or lack of efficiency depends and it is for providing the necessary air that we erect tall chimneys, or install fans or blowers.

The constituents of fuel which provide us with heat are carbon and the hydro-carbons. These latter are in the form of volatile gases, or in other words, gases that are distilled from the mass of the fuel, burning with a blue flame, and forming carbon dioxide or carbonic acid gas. When these gases are distilled there is left the fixed carbon, or the solid part of the fuel, in the form of a charcoal or coke. This also disintegrates and burns away, leaving only the incombustible portions, such as ash or clinker.

Constituents of Coal

The principal constituents of coal are easily remembered by their initial letters, which may be written to form two very familiar words, thus NO CASH. The initials stand for nitrogen, oxygen, carbon, ash, sulphur, hydrogen. Of these, it is only the carbon and hydrogen that furnish us with heat. The nitrogen is inert, the oxygen forms, in conjunction with part of the hydrogen, into water, and therefore causes a loss of heat proportional to its weight multiplied by its latent heat. The sulphur has a slight heating value, but it is detrimental in other respects. It is a very small portion of the total weight of coal.

Classification of Fuels

Fuels are classified generally according to the amount of fixed carbon they contain. Coal is broadly divided into two main classes, anthracite and bituminous. The anthracite group contains a very small percentage of volatile matter, being from 90% to 96% carbon, while bituminous contains only 50% to 70% carbon, the balance being volatile matter. This percentage applies only to the combustible material, the ash and clinker being neglected. This, of course, is only for purposes of comparison, the incombustible portion of the fuel being a very important part, as it has to be paid for, although it is of no use.

The ash content of both bituminous and anthracite coals varies very much, being as low as 3% in some kinds of bituminous, and as high as 20% to 22% in some anthracites. The heat value of a pound of coal will vary as the proportion of hydrogen and carbon it contains to the incombustible portions. The oxygen will unite with the hydrogen in the proportion of eight parts of oxygen to one part of hydrogen to form water. From this the well-known formula, known as Dulong's formula, from the name of the deducer, is evolved, and is as follows:

If h=heat C=% of carbon, H=% of hydrogen, and 14600=the heat value of one pound carbon, 62000=the heat value of one pound hydrogen. Then

$$h=14600\ C+62000\ (H-\tfrac{1}{8}O).$$

The constituent parts such as sulphur, ash, nitrogen are neglected in this formula as being of no use in furnishing heat. In analyzing coal for heat value it is usual to furnish a proximate analysis, and an ultimate analysis. The first gives the composition of coal in terms of its moisture, volatile matter, fixed carbon and ash, while the latter gives details of sulphur, hydrogen, carbon, nitrogen and oxygen, and the heat value is given from these. The actual heat value can be determined in the laboratory by experiment, but neither the heat value as determined by the calorimeter, nor the heat value as determined from the analysis, is a guide as to the heat value they will give in the furnace. Chemical analysis is a good guide in purchasing coal, and also as furnishing a standard for the quality, but it must be remembered that the heat value given by analysis and calorimeter test is based upon perfect combustion. That, as we know, is practically never obtained, although it can be closely approximated under favorable conditions. Supposing we have a coal containing 5% hydrogen, 76% carbon, and 9% oxygen, the remaining 10% being ash and nitrogen, then by Dulong's formula, the heat value will be

$$h=14600\times.76+62000\ \left(.05-\frac{.09}{8}\right)$$

$$=11096+2309$$

$$=13495$$

This is a fair sample of Pennsylvania coal of the bituminous variety.

Quantity of Air Required

We have spoken about getting as near as possible to conditions of perfect combustion, and in order to get this we must know exactly how much air is required per pound of coal to give the proper amount of oxygen. Oxygen is the gas that supports combustion and deprived of oxygen, combustion fails. The atmospheric air is the vehicle which carries the oxygen, and therefore we must supply air to the furnace in order that the carbon can receive the requisite amount of oxygen. The other constituent of the air, nitrogen, is of no use to us, and not only that, it has to be heated to the temperature of the other gases, and in doing so extracts heat from the furnace, which it carries up the chimney. Therefore, we must keep the air down to the lowest possible limit. We know that theoretically the amount of air required to burn one pound of coal is about twelve pounds. This is found from the quantity of air required to supply the oxygen to burn one pound of carbon, when they are thoroughly mixed. The oxygen required is 2 2-3 lbs. per pound carbon, and in order to get this quantity of oxygen we are forced to carry 3.32 times that amount of nitrogen, or 8.85 lbs. The sum of the oxygen and nitrogen is then 2.66+8.85=11.52 lbs. Air is composed of 21 parts oxygen to 79 parts nitrogen by volume, and about 23 to 77 by weight.

This theoretical quantity of air must be largely exceeded in practice, owing to the fact that furnace conditions do not allow of the perfect mixture of the oxygen and carbon. It simply means that in order to ensure getting enough oxygen, we have to supply a surplus amount. If it were only oxygen we supplied, it would not be so bad, but we have to bring in the useless nitrogen as well. The amount of excess air actually required is from one and a half to twice the theoretical amount. The quantity can be closely checked in a plant where there are flue gas recording analysers, but in a plant where these useful instruments are not on hand, it is not so easy. It is not within the scope of this course to go very deeply into the CO_2 question, and therefore we will pass over it with a brief description. When carbon is burned with the exact amount of oxygen it requires, then the product of combustion will be carbonic acid gas, or CO_2. If one pound of carbon requires 2.66 lbs. oxygen, and this oxy-

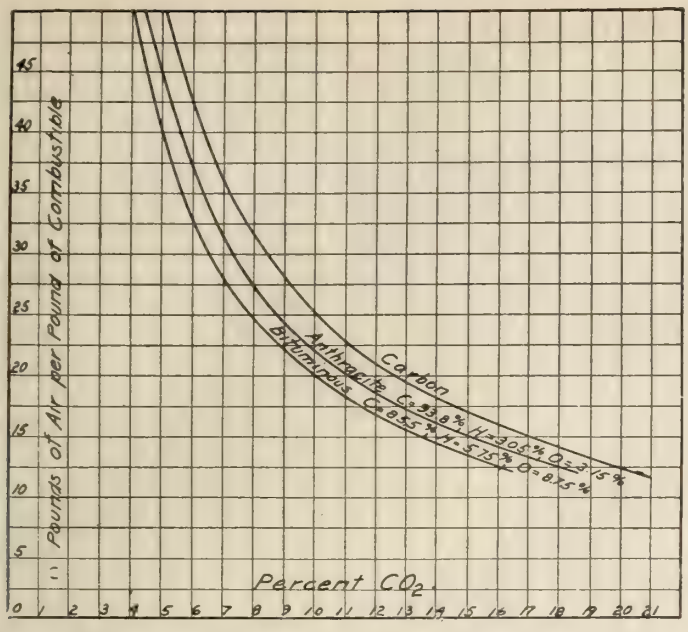

CHART SHOWING POUNDS OF AIR AND PER CENT. CO(2).

gen is supplied through the medium of atmospheric air, the oxygen present will be 21% of the total air, which is 11.52 lbs. Now when the carbon and oxygen unite to form CO_2, they occupy exactly the same space as the oxygen occupied formerly so that the proportion of CO_2 gas to the total amount of flue gases is exactly the same as the proportion of oxygen was to the atmospheric air. Well, then, if instead of the necessary quantity of air we have twice as much the same amount of CO_2 will be formed, but it will only be in one-half of its former proportion. That is, instead of being 21% of the volume, it will only be 10½%. From this we can easily see that the quantity of CO_2 in the flue gases is a direct measure of the excess air. Suppose we find we are getting only 5% CO_2. Then we are only getting 5-21 of the possible, or 23% of the full amount. Then, dividing 100-23 gives us 4.3, which means we are getting 4.3 times the excess air or about 50 lbs. air per pound of coal.

In practice, due to the presence of hydrogen in the fuel, it is not possible to obtain the full 21%, but a mark of 16% should be aimed at. The CO_2 recorder is without question the best means of checking fuel waste we have, and they should be in every plant where fuel consumption is of interest. However, where they are not in evidence, the careful engineer can use other checks.

Draft Gauges, Etc.

We spoke last week of the use of draft gauges, in connection with the efficient working of the boiler. If a flue gas thermometer is available to use in conjunction with them it will be found of great value. By comparing flue gas temperatures with different settings of the damper, and noting whether a change gives lower or higher temperatures, with the same condition of fire, a setting of the damper for all conditions of load can be developed, and marks made to set it to. Draft should never be checked by the ashpit damper, but always by the chimney damper. Further, the chimney damper should never be absolutely shut, but sufficient opening to carry away the gases should be left. There have been disastrous gas explosions through this cause. The damper being closed, there is no escape for the unconsumed gases rising from the coal bed, which is thus turned into a gas producer. This condition lasts for some little time, until there is a good accumulation of rich gas. The fireman then opens the damper wide, admitting a large quantity of air, which supplies the oxygen necessary for complete combustion, and this takes place so rapidly as to cause an explosion, which very often results in the demolition of the brick setting. This is a fairly frequent occurrence in boilers burning wood refuse, as shavings and sawdust, particularly when burnt directly under the boiler, instead of in a Dutch oven.

Intensity of Draught

The intensity of the draught, or the height of the water column, will depend on the resistance of the fuel bed and passages of the furnace. Thus a very small grade of coal which lies close on the bars needs a greater pressure to force the air through it. Burning this kind of coal on the ordinary grate presents a difficulty in that with a thin fire there is a great tendency to blow holes in the bed of coal which provide a short circuit for the air. On the other hand, a thick fire requires a very high draught pressure. It is for this reason that the burning of very small grade anthracite, such as No. 3 and 4 buckwheat and fine, cannot be successful without a suitable mechanical stoker.

With a coal high in volatile matter, which is a coking coal, the best method of hand firing is to keep the green coal towards the front, making the fire a little heavier on the front end. The air rising through the glowing carbon at the back is heated up, and the gases distilled from the green coal thus meet with a strata of high temperature air, which allows them to ignite. A low boiler setting with this kind of coal is especially bad, as it causes the freshly distilled gases to be cooled down by striking the boiler shell before ignition takes place, thus allowing them to pass out unburnt. The object of the refractory arches over most mechanically-fired furnaces is to ensure the ignition of these gases before they strike the heating surfaces. Ample combustion chambers allow of a thorough mixing of the gases with the air, which is a necessity if complete combustion is to take place, and also tends to lower the velocities of the gases.

Temperature of Flue Gases

The temperature of the gases leaving the last pass of a boiler forms a good indication as to the completeness of combustion, if heating surfaces are clean. They should be ideally about 100 deg. higher than the temperature of the steam in the boiler, but in practice are usually more. If furnace conditions appear good and the temperature of the escaping gases is too high, it is an indication of dirty heating surfaces, as the boiler is not capable of extracting the heat from the gases in their passage through the boiler. Low CO_2 will usually be accompanied by low flue gas temperature, owing to the large quantity of air to be heated up. Insufficient air will be indicated by a dull appearance of the fire, and low CO_2.

Many hand gas analysers have bottles for determining percentages of CO and O, which are carbonic oxide and oxygen, but these determinations are not usually necessary to the operating engineer. Generally, if the CO_2 is right, other conditions will be right also, and if the boiler is operating at an average of 12 per cent. CO_2, pretty good results are being obtained.

A device for continuously removing sand from water in hydro-electric works, to prevent the serious wear which is caused by its passage through the turbines, was recently described in "Le Gènie Civil." The apparatus consists of a series of parallel compartments furnished with baffle plates to prevent rapid motion of the water, which enters at one end at the bottom, and after traversing the compartments, escapes at the other end at the top. The sand and gravel fall to the bottom of each compartment, which is funnel-shaped. At the apex of the funnel a hole is provided through whicha small quantity of water constantly escapes, carrying with it the deposits. Thus the compartments are automatically cleared of sand.

A Boiler Room Load Indicator

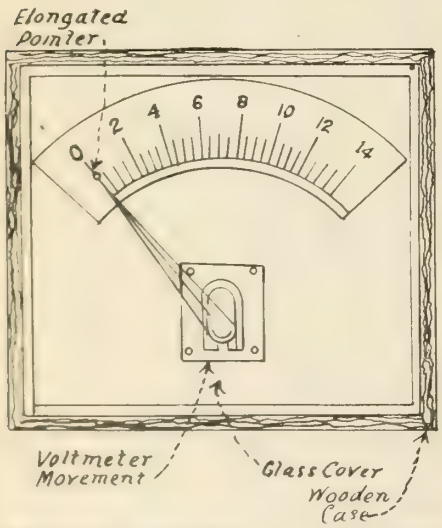
By T. G. CROSSE

(Copyright, All Rights Reserved)

The central station company that operates in one of our larger cities has installed in the boiler rooms of certain of its plants indicators whereby the boiler attendants are advised graphically of the kilowatt load on the station at different periods of the day so that they can handle their fires accordingly. The arrangement comprises merely three voltmeters, one in each boiler room and one at the switchboard operator's desk, all of which are so interconnected with a source of current and a resistance that the switchboard operator can vary the indications of the voltmeters simultaneously and at will. All of the voltmeters have scales which have been altered to read kilowatt load rather than volts. When the operator desires to telegraph the fact that a change in load has occurred, he adjusts the resistance until the pilot instrument in front of him reads the number of kilowatts load then on the station. Then the other two instruments in the boiler rooms will indicate the same reading because of their being interconnected with and having the same calibration as the pilot instrument.

One of the boiler-room indicators is shown in Fig. 1. The circuit showing how the indicators are connected and operated is delineated in Fig. 2.

It is of material assistance to the economical handling of a boiler plant if

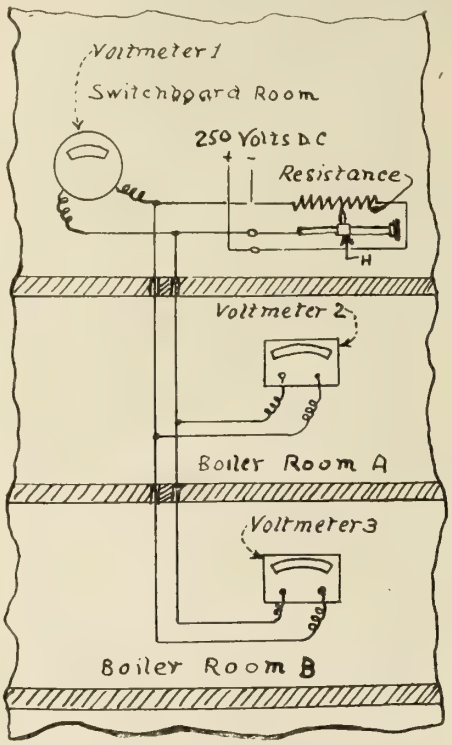


STANDARD VOLTMETER AS BOILER ROOM INDICATOR.

the stokers know the load that the plant is carrying. For example, if the stokers see by the indicator that the load is rapidly increasing, as it sometimes does when a period of darkness, due to a storm, ensues, or when it becomes suddenly dark in the evening, it is obvious that more boilers must be cut into service, or that those that are in service must be pushed to their maximum capacities.

Again, if the fire-room foreman sees from the position of the indicator needle that the load on the plant is decreasing, he immediately knows that he must cease heavy firing, and that possibly some of the boilers should be cut out of service.

The arrangement as used by this company is not automatic but is operated by



SHOWING WIRING OF PILOT METER AND BOILER ROOM INDICATOR.

the switchboard operator. In other words, the system of wiring the electrical instruments is merely an arrangement for transmitting a graphic message from the switchboard operator's gallery to the boiler room. The indicators used in the boiler room (Fig. 1) were made from Weston d.c. station voltmeters, altered into the form shown in the picture. The length of the pointer was increased from the usual 3 inch to 16 inch, so that the narrow end of the pointer would swing over a long scale that would be visible from any portion of the boiler room. This extension to the pointer was constructed somewhat in the form of a truss so that it would have maximum strength with minimum weight. The only portion of the original Weston meter that was retained was the movement, magnet and back board.

The scale of each indicator was divided into seven main divisions, and each one of these main divisions was divided into fourths. Assuming that each main division represents 20,000 kilowatts, the full scale deflection of the instrument would represent a load of 140,000 kilowatts on the station. Each subdivision represents a load of 5,000 kilowatts. The glass-front case enclosing each boiler-room indicator was made 2 ft. 9 in. wide and 2 ft. 6 in. high.

The switchboard operator has in front of him a standard round-type d.c. voltmeter, shown in the circuit of Fig. 2, which has its scale divided from 0 to 140, and has subdivisions, each one of which represents 5,000 kilowatts.

The resistance whereby the current through, or the voltage impressed on, the voltmeters is changed, consists of enameled wire wound on a spool.

A movable contactor is arranged to slide over the convolutions of this wire along a groove where the enamel has been removed. Thereby the contactor makes contact with the resistance wire. Electricity for the operation of the arrangement is furnished by a 250-volt storage battery used in connection with the exciter system.

It is obvious from a study of Fig. 2 that the switchboard operator can, by moving the adjusting handle H backward or forward so regulate the voltage impressed on the three meters 1, 2, and 3, that the three meters can be made to indicate simultaneously any value between 0 and 140,000.

When the load on the station is reasonably steady, the switchboard operator moves the adjusting handle occasionally so that the three indicators will show the load. However, at times when the load is changing rapidly or during the period of peak load, the operator shifts the handle every few minutes so that the fire-room force will always be conversant with the kilowatt load that the station is pulling.

SOME POINTS ON TURBINE MAINTENANCE

When it is considered that the losses in a turbine due to leakage and friction are only about 3 per cent. and 1 per cent. respectively, it is obvious that there is not a very wide field for the practical engineer to improve the efficiency. Reciprocators, on the other hand, usually provide plenty of scope for improvement when they are shut down, and this characteristic difference between the two types of prime movers is apt to result in the turbines being neglected, especially if the engines are troublesome or if the maintenance staff is limited. A thorough overhaul annually when the bearings, governor gears, blades and joints are attended to is generally sufficient to keep a turbine in good order. The rotor bearings will run much longer than the crank-shaft bearings, due to a practically even turning effort and the rotor being in equilibrium, as far as mechanically possible. That is to say, theoretically, the bearings only take the load due to the weight of the rotor and not a reaction load of

developed energy as in the reciprocator. This latter statement depends for its accuracy on the perfect dynamic balance of the rotor.

To secure long life and reduce maintenance charges on the rotor bearings it is most important to keep the rotating element balanced as perfectly as possible. Imperfect balancing causes reaction loads on the bearings, and sets up vibration, which is bad for the turbine, the floors and buildings. A well balanced turbo-generator set may develop an imperfect balance in time, due to either dirt on the rotor blades or slight movement of the generator rotor coils. Vibration will result when the bearings become worn, and allow the shaft to rebound in them. Sometimes it is difficult to distinguish the vibration caused by imperfect balance, or excessive bearing clearance, but when it is the latter the following rules generally apply. The vibration decreases as the speed increases, and when up to speed it further decreases as the load increases. It decreases as the excitation increases, owing to the restraining influence of the magnetic field.

All the bearings of a set do not wear down equally in practice, and it is very necessary to know how much each one wears if the rotors are to be kept in line. There should be a shaft gauge for each journal of every turbo set, so that the wear down to 1/1000 of an inch can be measured. A gauge can be made out of one-eighth in. sheet metal and used in conjunction with feelers. It is necessary to take measurements with the gauge in the same place each time, and keep a log of the figures for reference.

A frequent source of trouble is the electrolytic action which takes place at the bearings, and where a gunmetal worm-wheel is geared to a worm on the turbine shaft to drive the governor. The ends of the bearings and the sides of the gunmetal gear become spongy or pitter. The remedy is to fit a well earthed copper gauge brush to run on the rotor shaft, preferably between the generator and the centre bearing. Most turbine oils decompose to a certain extent with the heat and according to some authorities by electrolytic action. Water also gets into the oil and in time if means are not taken to remove the impurities, the percentage of good oil in the system will be reduced until the normal running temperature of the bearings will be exceeded. It is good practice to draw two or three buckets of oil from the bedplate weekly, filter it, put the clean oil back again, and make up the deficiency with new oil. Another method is to pump a bucketful of oil from the bottom of each compartment in the bedplate with a small pump such as those used in oil cabinets. This is advisable if there are any ribs preventing the flow of the bottom layers of oil to the pump section, and when there is water present.

Turbine casings are made of cast iron, but the annular steam chest at the high-pressure end is usually a steel casting, bolted to the casing circumferentially and split horizontally, so that the top half of the casings and steam chest can be lifted together, thus only breaking one joint. It is not always a simple matter to remake this joint after the turbine has been opened up. Steel expands more than cast iron when heated, and if the casing and steam chest are to make a fair joint at the working temperature, there will be a gap of a few thousandths at the steel joints when cold. Designers endeavour to overcome this difficulty by allowing for increased compression of the cast iron and increased tension on the cast steel, to enable a fair joint to be made cold, but the result is always not satisfactory. Another point which increases the difficulty is the tendency of the casing to warp during its early life; in fact large marine turbines of the Parsons type are steamed and allowed warp before the joints are finally machined. A lead wire joint is not always successful under such conditions, but by warming the steam chest as much as possible with the H. P. gland steam and keeping a good tension of the joint studs during the process, a tight joint may be obtained. The objection to this method is when the turbines are shut down there is excessive stress put on the joint studs, due to the steam chest contracting more than the casing, with the result that they frequently break. Bolts and studs subjected to high temperature as well as tension soon crystallize and become brittle; it is good practice to anneal these at the annual overhaul, and some spare ones should be kept in stock.

THE SAFETY OF LOW-PRESSURE STEAM CHESTS

A steam-heated drying chest in the drug room of a Manchester factory, which appeared on the face of it to be quite safe from explosion, nevertheless blew up in January last and injured the boy in attendance. In view of the large number of such chests in use in the country, we give below some notes taken from the Board of Trade report on the subject, and offer a suggestion for the safety device. The chest in question was 10 ft. long by 5 ft. broad and 3⅛ in. deep inside. It was made of boiler plate, ⅜ in. thick on the top and 7-16 in. thick below. There were three rows of riveted stays ¾ in. diameter, pitched about 9 in. apart. Steam was supplied through a ½ in. pipe fitted with a stop valve, direct from the boilers, which were worked at a pressure of 110 lb. per square inch. At the end of the chest opposite to the steam inlet there was a ¾ in. drain pipe, open at the end. There was no safety valve, reducing valve or pressure gauge on the chest. When the explosion occurred most of the stays fractured or tore out of the plating, the top plate bulged upwards, and split open round the riveted joint.

The only explanation of the mishap is that the drain pipe became choked up with dirt or scale, and that the steam pressure in the chest rose too high for the strength of the chest. The Board of Trade Engineer Surveyor-in-Chief recommends the fitting of a safety valve as a precaution against such accidents, and the chest which has been put in to replace the wrecked one is supplied with steam through a reducing valve, and it is equipped with a pressure gauge and safety valve.

Seeing that the trouble in the case under review, as with many others, was caused by the choking of the drain, which, had it been free, would have provided ample protection to the chest, we suggest that some means of ensuring the periodical clearing of the drain would be a satisfactory safeguard. Such a means might be provided by extending the spindle of the inlet valve so that it reached into the outlet. Then, whenever the steam valve was opened to admit steam the extension of the valve stem would disturb any dirt which might be lodging round the outlet, and ensure the drain being kept free. A U-tube a few feet high and filled with water would form a very effective safety outlet for such low pressure services as those under discussion, and would be very unlikely to get out of order.—The Engineer.

BIG STEEL PLANT SHUTS OFF QUICK

In Response to Demands That Claims of Railroad Men Be Met At Once

Sydney.—When 125 railroad employees of the Dominion Steel Corporation served an ultimatum on the management demanding a settlement of their wage differences before five o'clock the same day the company replied by closing down the various mills at noon and ordering the banking of the blast furnaces. This action automatically threw 4,000 men out of employment, pending the settlement of the dispute with the railroaders. It is estimated that it will require at least a week to get the furnaces in operation again, and it is believed that the big plant will be tied up for that period at least. The company, in the meantime, it is understood, is making application to Ottawa for redress under the provisions of the Industrial Disputes Act. It has been stated that lack of orders has been threatening the operations of steel plants for some weeks past. For the past two years the railroaders employed within the steel plant have been contending for the scale awarded all other railroaders in Canada following the McAdoo award in the United States.

Trying to Slip Through

WE recently received a letter from a correspondent, asking us if we could procure the questions asked by the Board of Examiners for second-class certificates, and furnish them to the correspondent. Needless to say, we neither can nor would if it were possible, accede to any such request.

The writer of that letter evidently misunderstands the purpose of an examination, or the benefit of an examination, or the benefit to be gained by passing it. A candidate for examination should know the subjects in which he is to be examined so thoroughly that any reasonable question should have no terrors for him. If a man presented himself for examination with the answers to a few stock questions committed to memory, he might succeed in passing, and obtain a certificate. There would be but little satisfaction to him in doing so, for he would ever have the fear that someone might come along and show him up for the fakir he really is. We do not think for a moment that we should be doing any man a kindness by trying to help him in that way.

The examinations are conducted by the examiners in a human sort of way, the object being to try and arrive at a reasonable estimate of a man's qualifications. The examiners are not trying to see if it is possible for a man to be rejected, but if it is possible for him to be passed. There is then, no occasion for a man with the requisite experience, and a reasonable amount of fundamental knowledge, to have any fear in presenting himself for examination before the Board. No man, who respects himself and his calling, will try to slip through the back way, but will present himself with confidence in his experience and ability to pass any reasonable test that may be imposed.

A Piece of Good Advice

WHEN Mr. Lloyd Harris told the business men of Canada not to depend too much on the Government, he spoke words of wisdom. We do not mean by this the present Government, the past Government, or the future Government in particular, but Government in general as an institution. A government is after all only a collection of ordinary men, who have attained prominence and position sometimes through merit, and sometimes through the fact that having no particular ability, they can be useful to the stronger men in the Government that have. These several men, whatever their abilities, upon attaining place, have their whole outlook on affairs tainted with the view of the office holder, whose primary object is to retain office, and do what he can for the country next. It is obvious that it is vain to look to such an institution for leadership in any vital trade or business development. In fact, any country which depends on its Government to advance its business interests is usually disappointed. It is the enterprise and daring of the individual trader that extends trade, and although a Government can carry out the wishes of the business community to a greater or less extent, it is very rarely that they suggest anything. Generally speaking, Government intervention in matters of business is usually attended with loss and inconvenience to those in the business, as has been abundantly shown in Great Britain by the Government control of shipping. Probably the only exception of note was Germany before the war, but it must be remembered that there they had no representative Government in the sense that we have. Therefore, they had men in the various departments of the Government, who were specialists, and not politicians. The Government holds about the same position in relation to the country that a chief office clerk or office manager does to a big corporation, and should not try to overstep that mark.

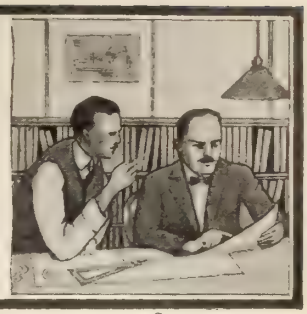
OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered



HEATING BUILDING

Question: Having been a subscriber to The Power House since its first publication, and having seen many difficult questions discussed and answered therein, I am taking the liberty to ask your assistance in a problem I have facing me. I have shortly to install a heating system in a frame building, 52 x 20, two storeys, 10 ft. ceilings. We have to be not less than 70 deg. I would like a formula for area of pipe coil or radiator surface per 1,000 cu. ft. air space (live steam)., 40 lbs. pressure.

Answer.—In a frame building the loss per square foot per hour runs from .23 B.T.U. to .44 per deg. difference between outside and inside construction. You might take the highest as a safeguard. Your wall area will be

$$52 \times 10 \times 4 = 2080$$
$$20 \times 10 \times 4 = 800$$
$$2888$$

and the roof $52 \times 20 = 1040$, which, added to the wall, gives a total of 3920 square feet. Allow for a difference of 80 deg., that is from 70 deg. to —10 deg. and the total loss per hour will be $3920 \times 44 \times 80 = 137984$ B.t.u.'s. This does not take into acount the ventilating, and if you wish to change the air once an hour, you will have to heat the cubic contents of the room from —10 deg. to 70 deg. In your two rooms you have $52 \times 20 \times 20 = 20800$ cub. ft.

One B.t.u. will heat 1 cubic foot of air about 56 degrees, so you will need approximately 1.5 B.t.u. per cubic foot air to allow for ventilation purposes. That gives 20800×1.5, which is 31200. Adding these two, we get 137984 plus 31200=169184, say 170000 rad. surface per hour.

You can allow 1.5 B.t.u. per hour per square foot surface per degree difference of temperature between coils and room. With steam at 40 lbs. the temperature is 287 degrees and with room at 70 difference is 217 deg. Then $217 \times 1.5 = 325.5$ B.t.u. per square ft. rad. surface per hour.

$$\frac{170000}{325.5} = 522 \text{ square feet rad. surface.}$$

This with 1¼ inch pipe would be about 1200 feet.

If the building is in an exposed position, additions must be made to cover the circumstances. Rooms with northerly exposure usually have an allowance of 10% extra. If building is allowed to cool over week ends, additional coils should be put in to bring it up to temperature quickly. These latter points are a matter for your own judgment.

BOILING UP TANKS

Question

I would like to get your advice on superheating steam for boiling water for dyeing and bleaching purposes.

We have one return tubular boiler working at 125 lbs. pressure. When they open four and sometimes six 1¾" valves at once direct into cold water, which has to be risen up to the boiling point, and boiled for an hour, with a perforated pipe going direct into the water, in these various machines you get nothing but saturated steam, and sometimes pulls the water over from the boiler, which starts priming and adds more water to the various liquors and also making same weak.

I have sent sketch showing proposed way of taking steam from boiler to superheater and from superheater to dye house. Please advise me as to pipes to be used in making up superheater and if it is necessary to have a drip from same. What effect would the flue gases have on the piping?

One reason for coming on to this superheater idea is that when they have got two or three machines on at one time it will pull the steam pressure down to sixty and seventy lbs. per square inch, which is too low for our other machines, and I thought this might help us out a little, and with the higher temperature bring our machines to a boil quicker.

Answer

The arrangement of sketch would not be suitable at all for superheating purposes. Copper pipes or tubes of small diameter would be absolutely necessary. Steam, contrary to water, is a very poor conductor of heat, and in using iron pipes of large diameter there would probably be a film of steam close to the walls of the pipe and relatively little motion. This would cause the pipes to burn out.

It would appear that the question is not one of superheating at all. If four one and a-quarter inch pipes are opened freely the quantity of steam escaping per minute would be roughly 557 lbs. This in one hour is equal to 33,480 lbs., and as one boiler horsepower at the pressure your boiler works at is equal to the evaporation of about 30½ lbs. of water per hour, this means that during the time these 1¼" valves are fully opened the boiler would have to work at 1000 h. p. to supply the steam. It is little wonder that under these conditions your steam drops very rapidly. Superheating would be of no benefit in a case like this, as the opening for the steam to escape would still remain the same. In the horizontal return tube boiler superheating may be of benefit in special cases, but as owing to the construction of the boiler the heat is being taken from the gases before they have fulfilled their work, extra fuel would be used for the superheating. Without knowing the conditions in your plant, it would be difficult to advise you exactly; however, would suggest that the remedy would be found in the application of reducing valves on the steam lines entering the tank, also reduction of area of the discharge pipe.

If the heating of the tank does not require to be performed very rapidly it might be possible to use steam coils instead of the direct mixture of steam and water. It has been my experience that in most cases in dyeing and bleaching industry the area of pipes used is usually altogether too large. The water is brought to the boiling point very rapidly, and no means are taken to regulate the temperature after the boiling point is reached. The result is that a large amount of heat is lost in evaporating water at atmospheric pressure, filling the room with steam for no useful purpose.

REVERSING AUTOMATIC ENGINE

Question.—Will you please explain how I could reverse an engine with a No. 2 Rites fly wheel governor. The engine is running over at present and I require it to run under. Please explain how it can be done in my next Power House.—W. F.

Answer.—With an automatic cut-off engine, it is sometimes possible to reverse the eccentric if the maker has made provision for same. With a Rites governor, the pin on which the arm is suspended would have to be moved to a position on the opposite side of the hub of flywheel. The pin driving the rod would be thus 180 deg. from its former position. The spring would have to be put on the opposite spoke of the flywheel. You would have to see that the

upper guides were strong enough to carry the load, as these are very often made much lighter than the bottom ones. A sketch of the engine would have helped us in answering this question.

SIZE OF CHIMNEY

Question.—Being a subscriber to Power House, I take this oportunity of asking your advice in regard to a problem I have before me. What size chimney will it take for a boiler 12′ x 52″, burning hard nut coal, heating a building 80′ x 45′? What size chimney using soft slack? Is it practical to use hard coal for return tubular boiler without forced draft?

Answer.—The area of the chimney you require should be about 1/9 the grate area, which would be about 2 feet. If it is a round chimney it would mean a diameter of about 24 inches, or if a square chimney 22 inches square. This area will be the same whichever kind of coal you use. It will be necessary in order to get the requisite draft burning small anthracite coal to have a very high chimney, about 160 feet. With soft coal, a chimney of 100 feet in height would be ample. I would suggest that you inquire into the cost of force draft apparatus, as against costs of chimney. Generally speaking, it is more economical to install force draft, as then you can burn a low grade coal and need only a short chimney.

Question.—An engineer holding a third-class certificate went overseas for three years, and continued with this same certificate on his return and worked under it for three years. Is he entitled to second grade certificate? Does war term lapse the certificate?

Answer.—Cases of this kind are decided at the discretion of the examiners, and an application will have to be made to them on special form, and the experience sworn to by affidavit.

SUPERHEATED STEAM IN STATIONARY PLANTS

In these days of the high cost of coal and labor, engineers are turning more and more to look carefully into the economies possible in the use of superheated steam.

When the heating of water in a closed vessel is continued after all the water is evaporated, it will be found that the temperature again begins to rise; and it will continue to rise as long as heat is added to it. Just at the point where evaporation is complete and the final rise in temperature begins, the steam is known as dry saturated steam. At any temperature above this point, we have superheated steam. In other words, when heat is added to saturated steam, it will become superheated; if heat be abstracted from saturated steam, it will condense. If pressure be released from wet steam, more steam will be formed; if the pressure upon it be increased, some will condense.

If saturated steam be withdrawn into another vessel which does not contain water, and further heat be applied, the temperature will increase and the steam will become superheated. It is evident that the temperature of the superheated steam will depend entirely on the amount of heat added.

The main advantage in the use of superheated steam results from the fact that its temperature can be lowered (depending upon the initial degree of superheat) without condensation taking place, resulting in increased economies of power plant operation.

Pioneers in the field of modern engineering realized from the beginning that cylinder condensation was the principal cause of low engine efficiency. Many devices were tried to reduce condensation. Jacketting the cylinder was tried and the engine efficiency was slightly increased. Superheating was also experimented with and great economies were obtained. The drawback was the difficulty of lubrication.

The introduction of compound engines and the use of high pressure steam back in the late '60's and early '70's combined to force the superheater temporarily out of the power plant field.

It was not until about 1895 that interest in superheating was sufficiently aroused to place it where it was a commercially possible power plant adjunct which gave practical economy.

The principal advantage of superheated steam in connection with reciprocating steam engines is in the reduction of the initial cylinder condensation. Initial condensation is seldom less than 20 to 30 per cent. of the total weight of steam entering the cylinder. Cylinder condensation may be reduced by compounding, which results in lower temperature difference between incoming steam and cylinder walls, or it can be done by the use of superheated steam, which allows the steam temperature to be considerably reduced before condensation begins. Even when compounding is resorted to, further reduction in condensation can be obtained by superheating. It is evident, therefore, that the use of superheated steam can very materially increase the economy of engines, whether applied to the simple, compound or triple engines, the amount of saving depending upon the type of engine. For a given amount of superheat the economies may be as high as:

40%—with slow running, full stroke or throttling engines.

20%—with simple non-condensing engines.

10%—with compound Corliss engines.

6%—with triple expansion engines, as compared with the same engines using saturated steam.

These figures are taken on a basis of steam consumption. It is, however, advisable to base results on the heat consumed per horsepower rather than on the steam consumption, since taking steam consumption as a basis, we are apt to receive a false idea of the relative economies. It must also be borne in mind that superheating requires a certain amount of additional fuel. The plant economy is, therefore, not in exact proportion to the increased economy of the engine alone.

In many power plants, the main units are operated on superheated steam, whereas the auxiliaries are operated on saturated steam, but as the latter are necessarily less economical than the main units, there would be much greater percentage gain resulting from the use of superheated steam. While the greatest gain in engines using superheated steam comes from reducing the initial condensation, a further gain will be made with higher degree of superheat, due to the steam being dry throughout the whole period of expansion.

In the case of the steam turbine, the initial condensation is less than in the steam engine, as the temperature difference between the entering steam and the turbine walls is lower, due to the fact that the steam has a continuous course through the turbine, whereas in the engine each end of the cylinder is alternately in contact with high pressure steam and then low pressure, resulting in an average lower temperature of cylinder walls.

In steam turbines, the question of friction or "windage" has a greater bearing on economy than initial condensation. The density of superheated steam is much less than that of saturated steam and hence the reduction in friction where superheated steam is used. Furthermore, there is the mechanical question of erosion of blades due to wet steam. Superheated steam is therefore almost invariably used for the operation of turbines.

Experience has shown that for efficient operation the modern superheater must meet certain requirements which may be summed up, as follows:

1. They must be located in the direct path of the gases without causing an undue amount of frictional resistance to the passage of the gases.

2. The surface should offer the least opportunity for the adhesion of soot or dust.

3. All parts should be readily accessible for inspection or repairs and the design should be such as to allow freedom of expansion without affecting the boiler or the setting.

4. Provision should be made for the protection against overheating when no steam is flowing through the superheater units.

5. It should give the maximum superheating efficiency.

6. It should be designed with careful consideration of steam velocities and steam areas to provide a minimum drop in pressure.

Progress in New Equipment

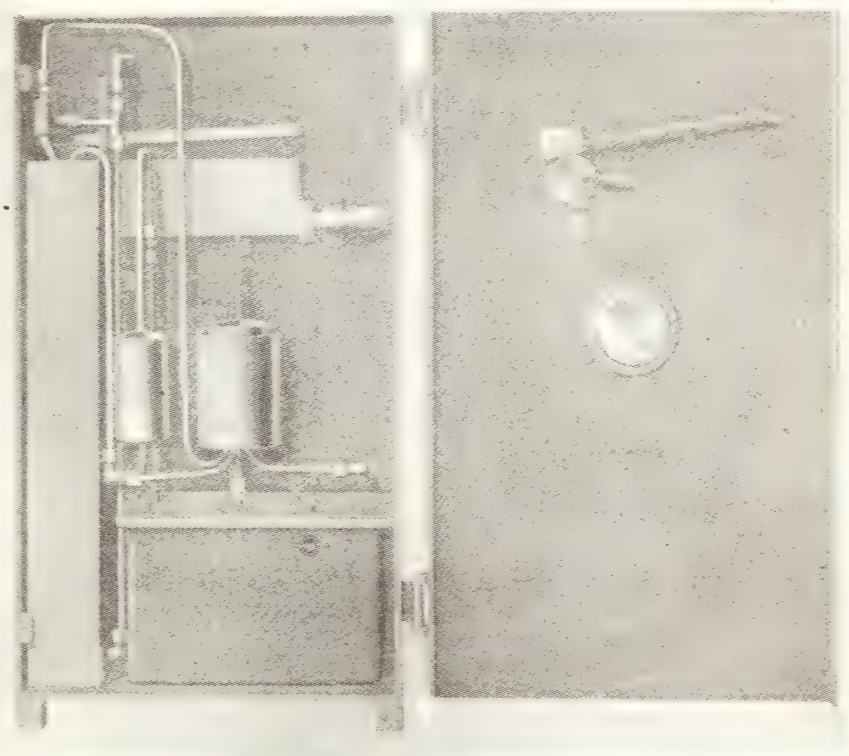
A NEW CO RECORDER

We have recently had the opportunity to inspect the CO_2 recorder, made by the Republic Flow Meter Co., and sold by the Republic Flow Meters Co., of Canada, 145 Wellington St. West, Toronto. The machine is well made, and possesses many points that will appeal to the engineer. It has been designed with a view to the conditions it will have to meet, and is of rugged and simple construction.

A few of the points claimed for the instrument are its simplicity of construction, which eliminates delicate parts and sensitive adjustments. No glass tubing enters into the construction, the necessary piping being of copper. The moving parts are limited to two, as can be seen from the detailed description, and furthermore no valves are used. The flow of gas is continuous, and the provision made for absorbing the CO_2 is ample. The machine weighs 45 lbs. and its appearance can be seen from the cut.

The details of operation are as follows:

When the CO_2 recorder is in operation, the water admitted at tube 1 flows through the loop in the oil seal for the purpose of maintaining constant temperature of the oil. It then passes vertically to the top of the case and follows through the jet 1b and aspirator 3 into the large container 5. The jet 1b forms a partial vacuum in tube 2 which draws the gas from the furnace.



MACHINE WITH CASE OPEN SHOWING RECORDING MECHANISM ON DOOR

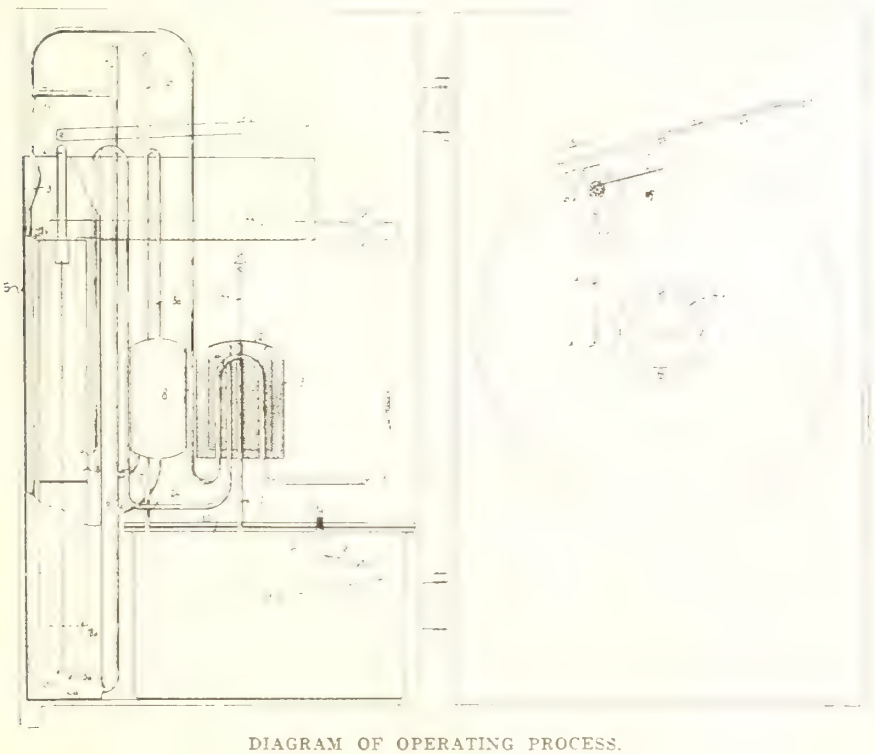


DIAGRAM OF OPERATING PROCESS.

The water rising in the large container also rises in the vertical tubing connected to the container at 5a. When the water reaches the branches 6 and 7, it seals off a definite volume of gas contained in the pipette 8. As the water continues to rise, it fills pipette 8, forcing the contents of the pipette through the tube 8a into tank 10, containing the potash solution. The gas passes through the potash solution under the entire length of the baffle plate in the tank and rises to the surface. This action absorbs all the CO contained in the gas, leaving an amount of residue gas which escapes through outlet 11 and raises float 12 to a height proportional to the amount of residue gas.

As the water continues to rise in reservoir 5, it overflows into float 18, causing the siphon system to sink. When the siphon system sinks, the water is siphoned out through tubes 22, 23 and 23a connecting with waste pipe. As the water level is lowered below point 9, it

releases the seal of the tube leading to the inside of float 12. The float lowers to rest on guide 11 and discharges the contents through the opening 9.

As the receding water reaches point 7, pipette 8 discharges through point 6,

SHOWING CHART.

drawing a charge of gas from tube 2. When the water recedes to point 23, air is admitted and the siphon action stops. The container begins to fill again, repeating the operation.

The recording mechanism is mounted on the door. When the door is closed, arm 14, rigidly connected to recording pen staff, swings into position directly over the rod 12a, and trip 15b mounted at the end of arm 15a is directly over point 21 on the siphon system. The trip is engaged when the siphon system sinks and raises weight 15 so that arm 14 is free to rest on rod 12a. Weight 15 is immediately released and its contact with 16 holds pen in position of the analysis. This exclusive feature of the Republic gives a continuous chart record, and the added feature of an indicating instrument.

THE PETROLEUM SITUATION IN THE CAUCASUS

The scarcity of the petroleum oils and the rising prices of the same in this country give a special interest to a report that has been made on the petroleum situation in the Caucasus by M. Aldebert as published in Le Geine Civil.

Communication with the oil regions of the Caucasus, which was becoming more and more difficult since 1914, was cut off entirely in 1917 because of Bolshevism and the Turco-German occupation. At the present time we are still very poorly informed on the subject. Widely different and contradictory reports are in circulation, and the report of M. Aldebert sets out to classify the situation as it existed on January 1, 1920.

Almost the whole of the Russian oil production comes from the Caucasus. In 1916 this amounted to about one-sixth of the total production of the world, and ranked Russia as next to the United States as a producer of mineral oil.

Although the Caucasus forms a continuous oil-bearing basin, for indications are found upon both the northern and southern slopes of the mountains, M. Aldebert divides the territory into three sections where the principal developments are concentrated:

1. The Maikopp section, which yields about 1.2 per cent. of the Russian output.
2. The Grosny section, which yields 17 per cent.
3. The Baku section, yielding 78 per cent.

In the Maikopp section, which is divided into three groups, there are 138 wells, of which only 38 are worked. These have a daily yield of about 67,000 gallons. The principal group at Maikopp is connected with the refineries at Ekaterinodar by an 8-inch pipe line about 87 miles long. The other two groups are connected by pipe lines to the tanks on the Ekaterinodar and Nova-Rossisk railway. The production of the Maikopp section rose from 503,000 gallons in 1908 to 47,140,000 gallons in 1912, but fell to 10,309,000 gallons in 1916, while in 1919 the output had again risen to 15,400,000 gallons.

These operations have suffered very little from the war, being situated in the centre of the provinces of Couban and Tereck, where the population is Cossack and, from the very outset of the revolution, have resisted the Bolshevik movement and have made up the nucleus of Denikine's army.

At Grosny the section is divided into two parts, that of the Old and New Rayon, located at a distance of about 9 and 3 miles, respectively, from the city. The operations at Old Rayon have not been destroyed, either by the revolution or the uprising of the populace, but at New Rayon the operations have been almost totally destroyed.

In November, 1917, seven flowing wells were fired and burned until February, 1919. Some of these wells had a yield of more than 283,000 gallons a day. An immense layer of lava produced by the burning oil covers the slopes of the hills to a depth of more than a foot. This lava consists of a petroleum coke and is actually used as a fuel under boilers. The wells which were not burned were destroyed with the axe and dynamite.

At New Rayon, out of 122 wells which existed before the revolution, only 5 are now being worked; 7 are being repaired, while the others are idle or have been abandoned.

The operations of the Grosny basin were begun in 1896, and grew continuously, except for a slight fluctuation during the first revolution of 1906, and reached a total yield, in 1917, of 550,300,000 gallons; but it would have reached 786,000,000 gallons had transportation facilities been sufficient.

In addition to tank cars there were 8-inch pipe lines leading from the district to the Caspian and Black Seas which, before the war, had a daily capacity of 10,310,000 gallons, while to-day, after repairing the pipe line destroyed in 1917 and the two pumping stations out of four, the capacity is only 471,000 gallons a day.

At Baku the production of the Akcheron peninsula, which was 258,000,000 gallons in 1882, steadily increased until it reached its maximum of 3,457,000,000 gallons in 1901. The revolution of 1905 cut the production of this section down to 2,106,000,000 gallons, but as matters became settled it rose to 2,467,000,000 gallons in 1916, although the scarcity of repair parts, machinery and material began to make itself felt in consequence of the war and the closing of the Dardanelles. The year 1918 brought in anarchy, and industry was completely paralyzed.

The year 1918, with a production of 630,000,000 gallons, saw the nationalization of the petroleum industry, followed by a Turkish occupation after several days of bombardment with its horrors and massacres. The economic disorganization is complete; there are now neither new operations nor exportations, and output is reduced to a minimum, so that we have to go back to 1889 to parallel it.

At the end of 1918 English and Russian troops occupied Baku anew. It had suffered from bombardment, but the operations were intact.

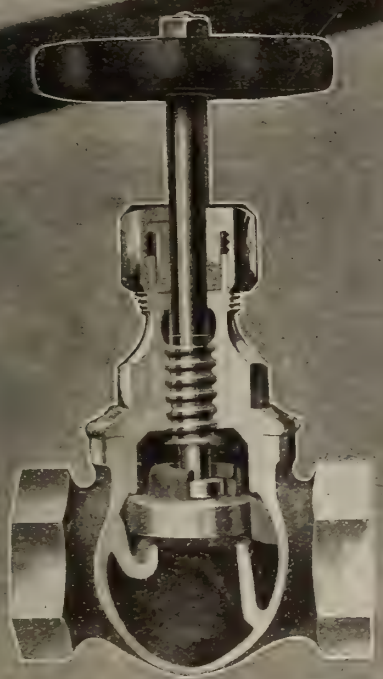
In 1919 a Tartar government was established, which later became the Republic of Azerbeidjan and was actually recognized by France. When order was established in August, 1919, the English evacuated Baku and, contrary to the forecasts, there were no massacres and no disorder.

But oil production was reduced to a minimum because there were almost no exportations, Astrakan being in the hands of the Bolsheviki, and Astrakan, before the war, handled about 75 per cent. of the Baku exportations.

In order to span this crisis the government advanced money to the operators in order to enable them to carry forward new operations, but as the tanks are full the situation is a difficult one. The exportation of oil from Baku is greatly reduced because of the lack of railroad transportation and the difficulty of passing through Georgia. The estimated production for 1919 is 1,257,000,000 gallons.

The average production of wells, which was 4,400 gallons per 24 hours in 1904, was 1,445 gallons in 1917, 1,165 gallons in 1918 and 1,730 gallons in 1919. Since the war the drilling of new wells has shown a constant decrease, falling from an average of 37,720 feet per month in 1913 to 13,120 feet at the end of 1917 and

FAIRBANKS-MORSE



An Achievement in Mechanics

EACH individual department of The Canadian Fairbanks-Morse Company, Limited has given industrial Canada a new conception of achievement in mechanics. Each department has established a 100% quality and service standard. This is what enables Fairbanks valves to stand pre-eminent wherever valves are used.

When an engineer specifies Fairbanks valves, he knows that he has selected not only quality of material but workmanship that guarantees perfect operation.

He is satisfied with the reputation and service of the institution that stands behind them. He acknowledges an achievement in mechanics.

Wherever pipe lines are laid—in Canada's great industrial plants—in her immense water systems—in mines and mills—Fairbanks valves are giving a service that is marked by the 100% seal of quality, the standard of The Canadian Fairbanks-Morse Co. Limited.

Our nearest branch will give you the benefit of this service, Our experts will help you in selecting valves and everything mechanical that you require. Make our catalogue your buying guide.

1,400 feet at the end of 1918. For 1919 the average is still lower.

Meanwhile living expenses are very high, materials scarce and high priced; though the government is making every effort to relieve the situation, which is one that affects the industries of the whole world and especially those of the United States by the unprecedented demand the low output of the Russian oilfields causes to be placed upon those of the United States.

LUBRICATION AND THE GERM PROCESS

The following is a synopsis of a paper on "Lubrication and the Germ Process," by Henry M. Wells and James E. Southcombe, M.Sc., read at the British Association meeting:

The authors draw attention that the modern view of lubrication on the physico-chemical side is the existence of a residual valency or affinity between the oil and the solid surfaces of the bearing and journal. The problem has, therefore, to be considered as a kind of intimate relationship between the oil and the metal. This is quite a different view to that held by investigators in the past, who thought that the property of "oiliness" so strongly manifested by fatty oils as compared with mineral oils resided in some particular physical characteristic of the oil itself. The modern point of view has been elaborated recently by a number of students of the subject.

The authors have discovered the reason why the fatty or fixed oils possess superior friction-reducing properties to that of mineral oils. They have shown that this is due essentially to the presence in fatty oils of minute quantities of free fatty acids, which are absent in the majority of mineral oils. In consequence of this discovery they have added small quantities (about 1 per cent.) of fatty mineral or organic acids, which are easily accessible and relatively cheap to hydrocarbon oils. The products so obtained possess remarkably low frictional co-efficients. As an example, the addition of 2 per cent. of common fatty acid to a mineral hydro-carbon oil reduces the coefficient of friction shown by this oil on a friction testing machine from 0.0084 to 0.0052—a diminution of 26 per cent.

By suitably choosing the type of fatty acid to be added to mineral oil, the behaviour of oils in the presence of water and other contaminating substances can be modified at will. It is also shown that the risk of metallic corrosion is even less with these oils than the usual compounded oils, because the latter frequently develops in working notable quantities of free acid.

The principle of making mineral lubricating oils possessing increased frictional properties by adding to mineral oils suitably chosen fatty acids in relatively minute amounts has been patented throughout the world, and has been somewhat fancifully called the "germ process," because the fatty acid is the germ of the idea.

The value of the process lies in that oils possessing friction-reducing properties much superior to mineral oils can be prepared at relatively little extra cost to mineral oils. Secondly, by this means an immense quantity of fatty oil suitable for the manufacture of margarine and other foodstuffs is liberated for the country's needs and substituted by a much smaller amount of commercial fatty acids, which are quite unsuitable for food and are more or less in the nature of a by-product.

Finally, it may enable the lubricating oil manufacturer to produce the highest class of friction-reducing oils from comparatively thin — therefore cheaper — mineral oils, and incidentally this may have the utmost significance to-day, when we are striving to foster and develop the mineral oil production of our own country and the Empire.

INTERESTING CATALOGUES

The Canadian Blower and Forge Co., Ltd., Kitchener, Ont., have issued a new catalogue, No. 19C, dealing with their varied line. This includes forges, blowers, exhausters, fans, drills, punches, shears, binding machines, tire setters.

Combination wood working machines, fan system apparatus for heating, ventilating, drying and mechanical draft, air washers, humidifiers, dehumidifiers, pumps, etc., etc., are also shown. This book contains 186 pages of real, live information to those interested in such lines.

We have received from the Grover Corporation, East Chicago, Ind., their bulletins 501, 502, 507, 509, illustrating water filters and softeners. The filters are of the vertical and horizontal pressure type, the filtering medium being crushed quartz and silica sand. A coagulating tank is supplied when required, the coagulant being fed through a Venturi tube. The bulletins on water softening contain a great amount of useful information on this subject, especially regarding the chemistry of Zeolite water softening.

SUPERHEATED STEAM IN STATIONARY PLANTS

(Continued from page 530)

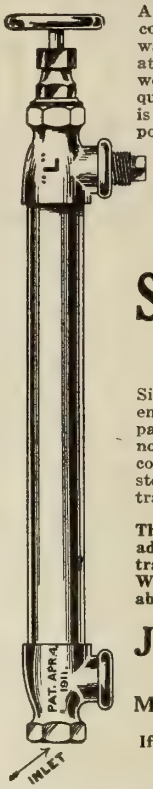
7. It should give uniform superheating and be designed for ease of regulation.

8. There should be a minimum possibility for leaks.

9. Its design should be such that it can be adapted to meet the individual plant conditions.

These considerations are vital to the success of the use of superheated steam. The high economies possible by the use of superheated steam warrant a careful study of conditions for each and every case where it is proposed to use it.

Power House Economy



A Steam Trap that saves coal by abolishing heat-wasting steam leakage, and at the same time does its work efficiently without requiring constant attention, is the trap you want in your power plant.

The Long Patent Steam Trap Fills the Bill

Simple, reliable and efficient. Has but one movable part. Automatic — requires no valves except those which control the admission of steam to apparatus to which trap is attached.

The Long Trap has several advantages over all other traps. Protected by patents. Write and let us tell you all about it.

NON-CORROSIVE CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
NOS. 242 244 SOUTH ST. NEW YORK, U.S.A.
FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done — give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

E. H. KELLOGG & CO.,
New York, U.S.A.

GALT FIRM GETS THIS BUSINESS

The Exchange Rate This Time Worked in Favor of the Canadian Firm

Irritation over United States exchange hold-up has been the means of securing for Messrs. Goldie & McCullough Ltd., of Toronto and Galt, a large order for boilers and heavy machinery for the new municipal lighting plant at Murwillumbah, Australia. Several American machinery manufacturers tendered for the business. The order is an important one. Mr. A. McArthur, of the Empire Engineering Supply Company, Sydney, Australia, at present at the Walker House, had the satisfaction of booking this order, and is expected to throw other important trade to Canadian manufacturers.

Mr. McArthur is now in consultation with officials of the Canadian Manufacturers' Association, urging that organization to inspire greater activity among its members to take advantage of present opportunities and lay the foundation for a large volume of the Australian trade. The Antipodean Commonwealth now has a tariff of 40 per cent. against all importations foreign, with a preference in favor of Great Britain and such of her Dominions as are on the same plan as Australia with respect to white labor conditions. Mr. McArthur says that if Canadian manufacturers are prepared to quote reasonable prices in many lines of articles, Australia is in the market with a large volume of orders to be filled.

Trade Gossip

Coal Supply Easier.—With the arrival of colder weather officials of the Railway Commission at Ottawa, who are handling fuel control and distribution, are not apprehensive as to supplies, if the early winter weather proves reasonably good.

CLASSIFIED ADVERTISEMENT SECTION

TWO CENTS A WORD, including the "Power House" box numbers; minimum charge is $1.00 per insertion, for 50 words or less, set in 6 pt. type. Each figure counts as a word. Display ads., or ads. set in border, are at the card rates.

GOOD INVENTIONS

ENCLOSED LIQUID FUEL COMBUSTION APparatus capable of generating intense heat in pipes and confined passages for heating parts of internal combustion engines and for other uses; spark ignited; blower operated. Patented October 8th, 1918. Can be inspected at and for sale by H. W. Petrie, Limited, 131 Front St. W., Toronto.

EMPLOYMENT DESIRED

STATIONARY ENGINEER, SECOND-CLASS, requires position; thoroughly experienced with water-tube and return tubular boilers, Corliss and all classes of stationary engines compressors, electric motors and generators; heating systems and hydraulic. Apply, mentioning "Power House," to No. 67062, A. Wright, 298 Bathurst St.

RETURNED SOLDIER — EXPERIENCED painter, electrician and elevator operator, or other suitable employment; desires work at once. Apply mentioning "Power House," to Pte. (163466) Ira Charles Winckler, 83 Carlton St., Toronto.

RETURNED SOLDIER WANTS WORK—ANY kind; used to steam heat boilers. Apply, mentioning "Power House," to W. Greenfield (33065), 34 Brock Ave., Toronto.

BELTING

4½—4-PLY NEW CANVAS STITCHED BELTing at 30 cents per foot. We carry a complete stock of belting, pulleys and mill supplies. Apply, mentioning "Power House," to N. Smith, 138 York St., Toronto.

LEATHER AND RUBBER BELTING, USED, but in good condition; at about half new price. Apply, mentioning "Power House," to Tarshis & Sons, 400 Front St. East, Toronto.

WE HAVE A QUANTITY OF NEW RUBBER belting to sell at less than half price; will ship C.O.D., subject to inspection; new circular saws, good second-hand leather and rubber belting, wire cable, vises, chain blocks, garden hose, steam hose, rubber packing; send us your requirements; our quotations will surprise. Apply, mentioning "Power House," to The York Belting Co., 115 York St., Toronto, Ont.

SITUATIONS VACANT

WANTED — EXPERIENCED BOILER DEsigner by large manufacturing plant in Ontario. Apply Box 92120, Power House. (p12h)

WANTED—A1 GENERAL BLACKSMITH FAMiliar with mine and mill work; permanent position. Apply, mentioning "Power House," stating experience and wages wanted, to Moose Mountain, Ltd., Sellwood, Ont.

EQUIPMENT

THE JOHN INGLIS CO., LTD., ENGINEERS and boilermakers. Write us for prices. 14 Strachan Ave., Toronto. Mention "Power House."

WE BUY IDLE EQUIPMENT OR MACHINery; call or write. Apply, mentioning "Power House," to H. W. Petrie, Ltd., Toronto.

GRATE BARS

ALL STYLES TO ORDER—PROMPT DELIVery. The E. T. Lansdowne Foundry Co., 37 Niagara St., Toronto. Mention "Power House."

Goodyear Klingtite Belts driving the sugar cane crushers of Cuba, Mexico and Central America

Canadian Success Promotes World-Wide Sale

As a result of the way Goodyear builds and sells belting and industrial hose in Canada, you will find these Goodyear products saving and serving in over 1,000 of Canada's finest industrial plants and mines.

The analysis of conditions, the scientific specification and application of belts, which Goodyear men make in Canadian plants they are now making all over the world.

To meet the requirements of world-wide trade it has been necessary to make some changes in the names of Goodyear Belts.

For example, Goodyear Extra Power is now Goodyear Klingtite Belt.

But the change is a change in name only.

This world-wide use of Goodyear Belting and Industrial Hose, Canadian-made, will multiply many times the fund of data and experience available to Canadian Goodyear users.

The problems overcome and the lessons learned in the factories of Japan and China, in the mills of India, in the workshops of South America, in the mines of South Africa, by the industries of every country, can now be applied by Goodyear men to Canadian industrials.

When the Goodyear belting man comes to talk to you, this information guides him in advising with you. His help is valuable—and costs you nothing. Phone, wire or write nearest branch.

The Goodyear Tire & Rubber Co. of Canada, Limited

Branches: Halifax, St. John, Quebec, Montreal, Ottawa, Toronto, Hamilton, London, Winnipeg, Regina, Saskatoon, Calgary, Edmonton, Vancouver. Service stocks in smaller cities.

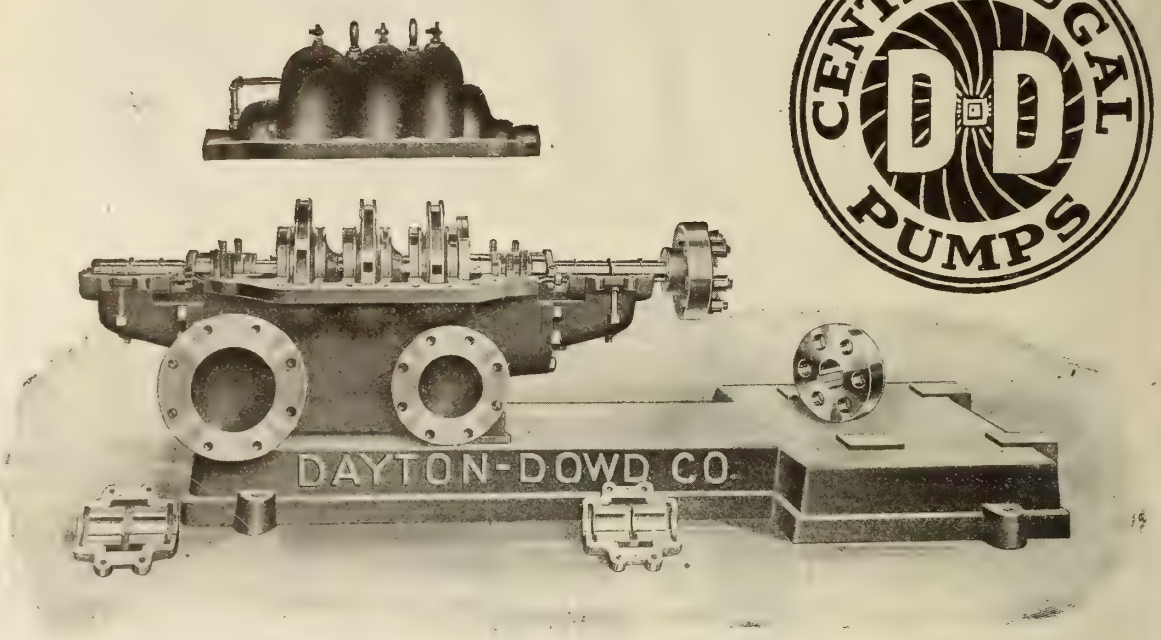
KLINGTITE GLIDE BLUE-STREAK



CENTRIFUGAL DD PUMPS

Dayton-Dowd Type CSU Automatically Balanced Three-Stage Centrifugal Pump

Illustration shows upper half of casing lifted. Note ease of access to all working parts. This is but one of the few points of merit of this type of Dayton-Dowd CSU Centrifugal Pump. Simple in design and rugged construction insures reliability in service and durability. Absence of diffusion vanes adds greatly to its life and reduces maintenance expense. Original and advanced in design and absolutely guaranteed to perform the service for which it is sold.

Type CS Single Stage, Double Suction Volute Centrifugal Pump

Non-overloading type, and so designed that the power consumed under any conditions of variation will not exceed the power required under normal operation. This feature protects the motor from being overloaded. This pump contains all the good features of Dayton-Dowd construction.

In Use in Prominent Plants

Parliament Buildings, Ottawa, two 2" type CSU, 2 stage centrifugal pumps.

Toronto Union Station, Toronto, eleven type CS, single stage pumps.

Corporation of New Toronto, two 8" CSU, single stage pumps.

Bridgeburg Water Works, Bridgeburg, two 5" single stage, type CS pumps.

St. Thomas Water Works Pumping Station, St. Thomas, three 8", 2 stage, type CSU pumps, each direct connected to 150 h.p. motors.

Acton Water Works Pumping Station, one 5", 3 stage, type CSU pump, direct connected to 75 h.p. motor.

Showing how V-Buckets not only Elevate material but act as Scrapers on the horizontal.

Jeffrey Standardized V-Bucket Elevator-Conveyer

For the Small Power or Industrial Plant

It is designed for coal handling in the plant calling for a run-around conveyer, where the capacity is less than 50 tons per hour, as given by our small pivoted bucket carriers. Especially adapted to the handling of slack and stoker-sized coal.

May be used either as a run-around conveyer or as a combined elevator and scraper, and where conditions will not permit of a vertical elevator being extended sufficiently high to spout the material to points desired.

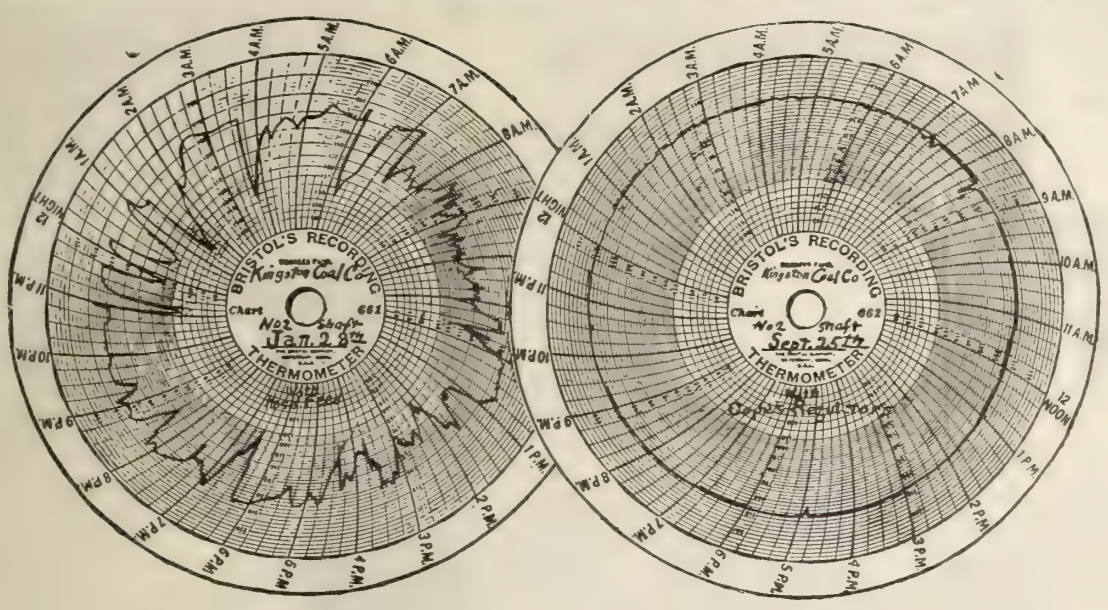
THE COPES SUCCEEDS

where all ordinary means of Boiler Feed Regulation have failed



BEFORE and AFTER

Records of one Plant where
A Reduction of 3% in Fuel Consumption
Resulted from the Installation of Copes Boiler Feed Regulators

Hand regulation cannot possibly give economical results, because the operator does not know until the gauge glass tells him a long time afterwards what is going on inside the boiler at any given time. **The Copes automatically responds instantly to every fluctuation in the boiler load.** It stores heat when heat should be stored. It utilizes all available heat for steam-making when that is necessary.

The two charts shown above are typical "before and after" records where hand regulation was superseded by Copes regulation. The left hand diagram, a record of hand regulation, shows an average feed water temperature of only 178° F. The right hand diagram, the result of Copes regulation, shows an average feed water temperature of 210° F.

The Copes therefore increased the average feed water temperature 32° F. This is equivalent to a saving of 3% of fuel.

Besides saving fuel and labor, and increasing boiler capacity, the Copes insures constant steam pressure, equalizes boiler load, makes meter charts legible, reduces wear and tear on piping, produces dryer steam, increases superheat, and frequently raises by 30 to 100% the peak load capacity of a boiler plant.

Write for our Bulletin D, giving detailed information and technical data.

AIR COMPRESSOR PACKING

The maintenance of an air-tight stuffing box on compressor rods presents a definite packing problem.

Garlock Style No. 222 is made with a center of flattened asbestos tubes not affected by the highest compression temperature developed.

Lubricated with the celebrated Garlock compound, this packing retains its resiliency under the most adverse conditions.

These rings are made up into sets to fill various depths of stuffing boxes.

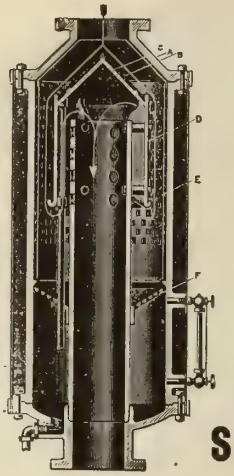
III IMPORTANT THINGS

TO CONSIDER ABOUT
A SEPARATOR



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE — Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION — Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

Sweet's Separators

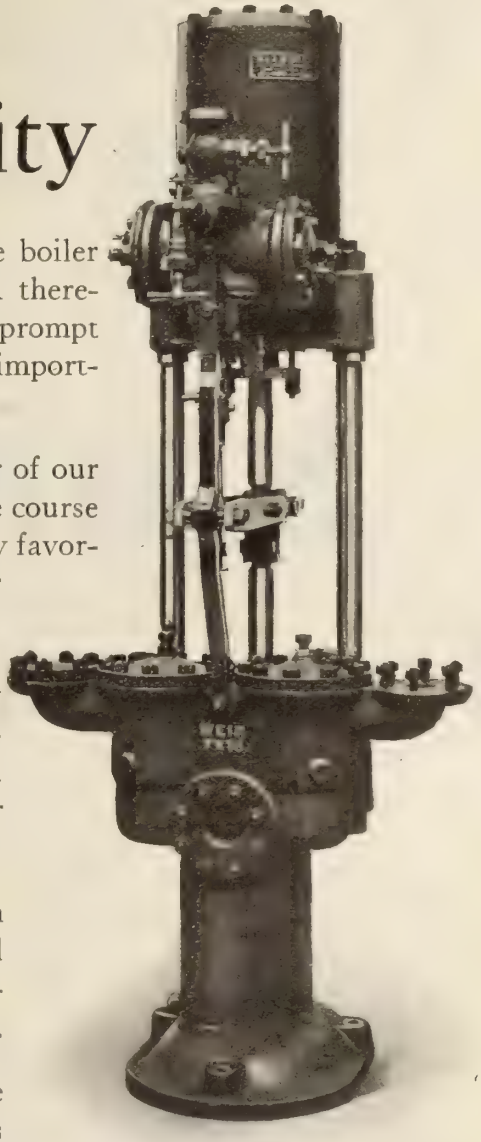
WEIR PUMPS

Delivery and Interchangeability

Any possibility of stoppage in the boiler plant is a serious matter. When therefore a new feed pump is required prompt delivery is usually of the greatest importance.

As we always have a large number of our standard pumps in stock and in the course of construction, we are in a specially favorable position to meet demands for urgent delivery.



Overhauling and renewal is greatly facilitated by our system of interchangeable parts and the fact that we keep in stock at all times parts for our standard pumps.

Special attention is paid to the prompt dispatch of goods and the routing and shipment of all consignments. Special instructions in this regard always receive our most careful attention.

Prompt and careful shipment is but a single phase of Weir Service. To serve our customers in every way to the best of our ability is our aim.

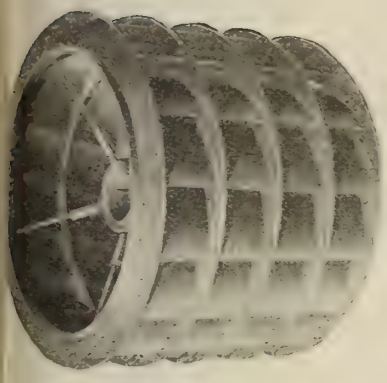
Head Office and Works:
Sales Offices: Toronto

Sturtevant
(TRADE MARK)

ler Ratings



The impellers are of exceptionally strong construction. The blades are made from heavy steel plate to true curvature and are flanged and riveted to the heavy supporting annular rings which are cut from the solid sheet and contain no weld or joint.

he cast hubs are riveted to center-plates and are prop-rly shaped to conform to the natural flow of air.

he impeller and shaft are carried by two high speed edestal type of bearings, which are supported inde-endent of the fan housing.

Consult our engineering department concerning your special forced draft requirements. Their recommendation may lead to important savings in fuel and labor. Write for Catalog No. 236P.

All There Is to a De Laval Boiler Feeder

This photograph shows a De Laval combined Turbine-driven Centrifugal Boiler-Feed Pump complete, with cover lifted.

A multi-stage centrifugal pump is mounted upon one shaft and enclosed within one casing with a steam turbine.

The only packings are two simple packings about the shaft. Contrast this with the numerous packings, including the piston rings, of a reciprocating steam pump.

The only lubrication required is for two ring-oiled bearings. Contrast this with the numerous oil cups and grease cups of a reciprocating pump.

The exhaust steam contains no oil and can be utilized in an open feed water heater or a heating system. With a reciprocating pump an oil separator would be required, with questionable reliability.

There is no pulsation in the pipe line, nor danger if the discharge should be suddenly cut off. Piping system and boiler check valves last longer, and boiler feed regulators and boiler feed meters can be used with satisfaction and to advantage.

The space occupied in comparison with that required by a reciprocating pump is insignificant. The 3000 boiler horsepower pump shown herewith occupies a floor space of only 3 by 2 feet.

As compared with the direct-acting pumps, less steam is used. Provision for regulating the number of nozzles in use make it possible to operate the turbine always at the highest efficiency.

Engineers who have had experience with the simplicity, reliability and reduced wear and tear incidental to De Laval Centrifugal Boiler Feeders, never return to reciprocating units. Ask for Special Publication No. N-100

Eight 250 h.p. Stirling Boiler, 160 lb. Pressure

FOR PROMPT SHIPMENT

Complete with Automatic Stokers and all necessary fittings

These boilers have new tubes throughout, making them as good as new.

The above are only a few items from our large stock of Steam and Electrical Equipment, consisting of TURBO UNITS, RECIPROCATING UNITS, ROTARY CONVERTERS, MOTOR-GENERATOR SETS, BOILERS, CONDENSERS, PUMPS, ETC. Complete list will be gladly mailed upon request.
Send for our special lists of INDUCTION MOTORS, new and used, as we have too many to list here.

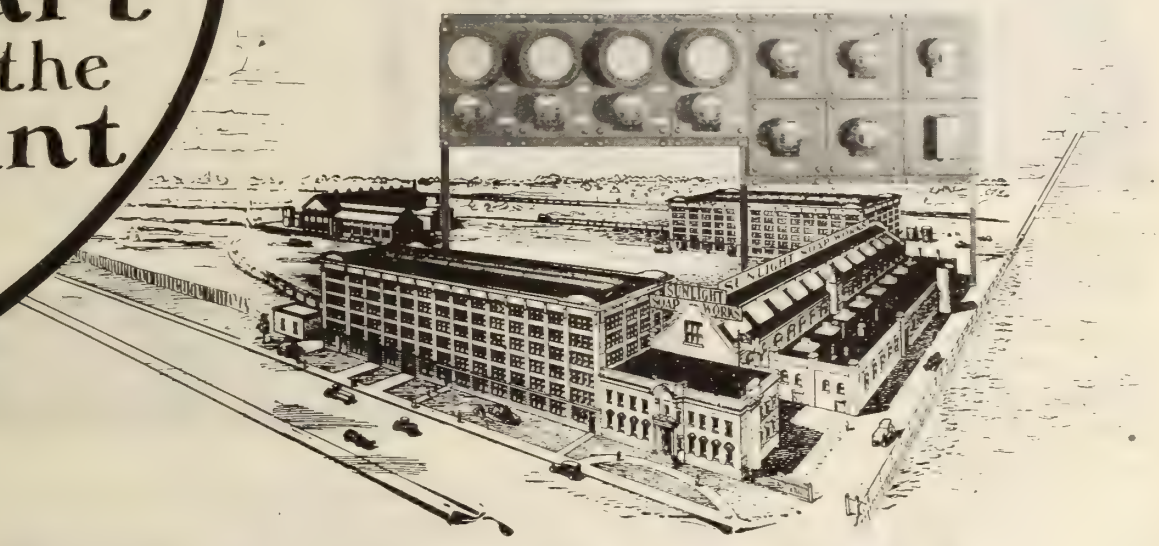
Republic

FLOW METERS

The Heart of the Plant



Good Results at Sunlight Soap Works

The great advantages of the Republic principle of electrical operation are well illustrated in the power plant of the Sunlight Soap Company, Limited, Toronto. The superintendent and the engineer should know what Republic Flow Meters have accomplished; read what they have to say:

Less Fuel Consumed

October 12th, 1920.

The Republic Flow Meter Co. of Canada, Limited,
145 Wellington St. West,
Toronto.

Dear Sirs,—We wrote you some time ago, shortly after your Meters were installed, advising that we were getting good results. The installation is now complete and we have many good figures to work with.

We have located leakages of steam which it would have been impossible to discover without the use of your Meters.

Our fuel consumption is being reduced daily and we hope by the end of the year to have yet more complete and lasting results.

The Meters paid for themselves the first week they were in operation.

We would be glad to furnish particulars to any of your customers who may require information.

Yours very truly,
LEVER BROTHERS, LIMITED,
(Signed) James Mess,
Works Superintendent.

One Boiler Less Needed

October 1st, 1920.

The Republic Flow Meter Co. of Canada, Limited,
145 Wellington St. West,
Toronto.

Gentlemen,—In reply to yours of the 29th enquiring as to the results we have had from Republic Flow Meters, I beg to state that since we have had the meters in operation I have been enabled to cut one boiler from use, and also by discovering leaks in lines. I have been able to carry over the week ends with one boiler instead of two as formerly.

We have been able to make great progress with the conservation of fuel by the application of the meters, and I am convinced that a plant without them cannot be economically run.

I shall be glad to show any person you may refer to me the charts, and prove to them the indispensable value of Flow Meters.

Yours truly,
LEVER BROTHERS, LIMITED,
(Signed) Wm. S. Ball,
Power Engineer.

The departmental lines are all metered, making possible a systematic distribution of steam costs. **Flexibility plus accuracy** is briefly the result of electrical operation. It means that Republic Flow Meters will conform to your plant conditions—it means that you can rely on the indications of the reading instruments. **Write for complete information of the benefits of the Republic Flow Meters in your plant.**

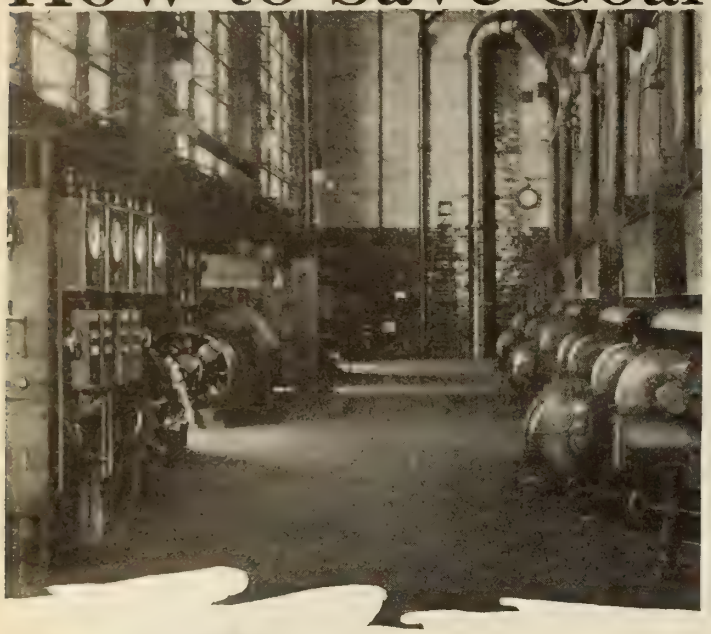
How to Save Coal



Tried on one Boiler—
Soon used on *all*

Many large Canadian plants are reaping a good profit from the savings effected by

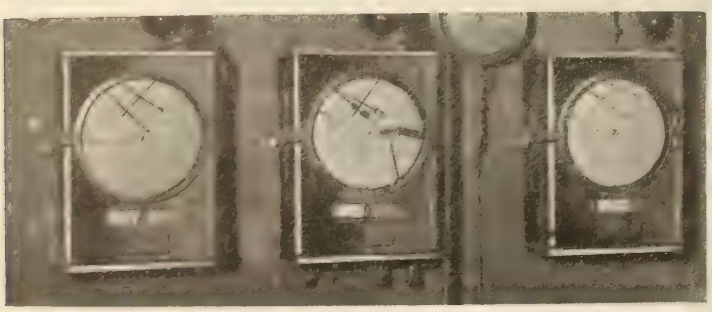
BAILEY
BOILER METERS

The "Bailey" is a watchdog of the coal pile. It prevents steam waste in the plant.

"Bailey" boiler meters show the true performance of each individual boiler, enabling you to determine which boilers are lagging and the number of boilers that should be cut into the line to carry the existing load at the highest overall economy. They show when a boiler needs cleaning or repairing and will serve as a check on the attention paid by the men to their firing and feed regulation.

May we consult with you regarding their application to your plant conditions? Ask for bulletins.

Bailey Meter Company
2001 E. 46th Street, Cleveland, O.



A MALLET, A TROWEL AND A BARREL OF
Betson's Plastic Fire-Brick

That's all you need to build substantial, crack-proof, airtight boiler arches, as well as line your furnaces better than you could ever hope to do with masonry.

Your handy man does the work and after a few hours' hardening your boiler is all ready for use. Our pamphlet describes this easy method and its many advantages. Send for it now, while you think of it.

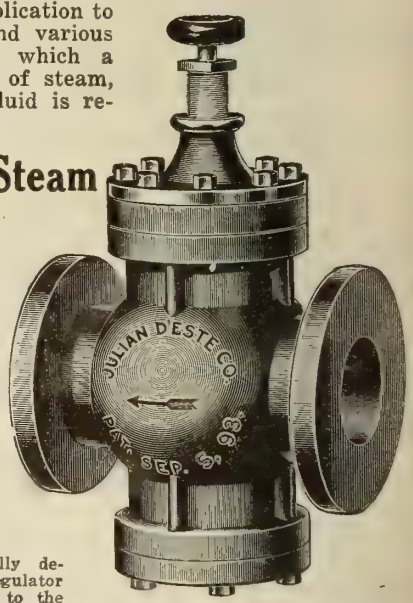
Universality!

For universal application to all the varied and various conditions under which a reduced pressure of steam, water or other fluid is required the

Improved Steam Pressure Regulator



has no equal.
It is compact and self-contained, without levers, weights or projections.
No glands or packing; no drip for leak of steam or water. Suitable for any boiler pressure; made entirely of metal: is a lock valve, very simple and sensitive.
Send for leaflet fully descriptive of this Regulator (contains price list) to the manufacturers.

Canadian funds are accepted at par at Montreal.

Let Riley Stokers Reduce Your Costs

Riley Stokers are always on the job—you can rely on them to be at work every day. They are tireless—working all hours of the day and night—without complaint.

Industrial plants can cut their operating costs to a minimum by using Riley Underfeed Stokers. Consider the following facts:—

EFFICIENCY—Boiler tests on Riley Stokers have shown over-all efficiencies of 80 per cent. and higher.

LABOR SAVING—One or two men can replace ten or twelve required for hand firing. Continuous, automatic discharge of ashes means elimination of drudgery in fire cleaning. Labor for ash handling in a well-laid-out plant is negligible.

COMPLETE COMBUSTION—The underfeed method and moving grates intimately mix the proper amount of air and coal, giving perfect combustion.

Catalog HR-12 sent on request.

For information on the Murphy Automatic Furnace for small plants, see last month's advertisement, or send for Murphy's catalog HM-12.

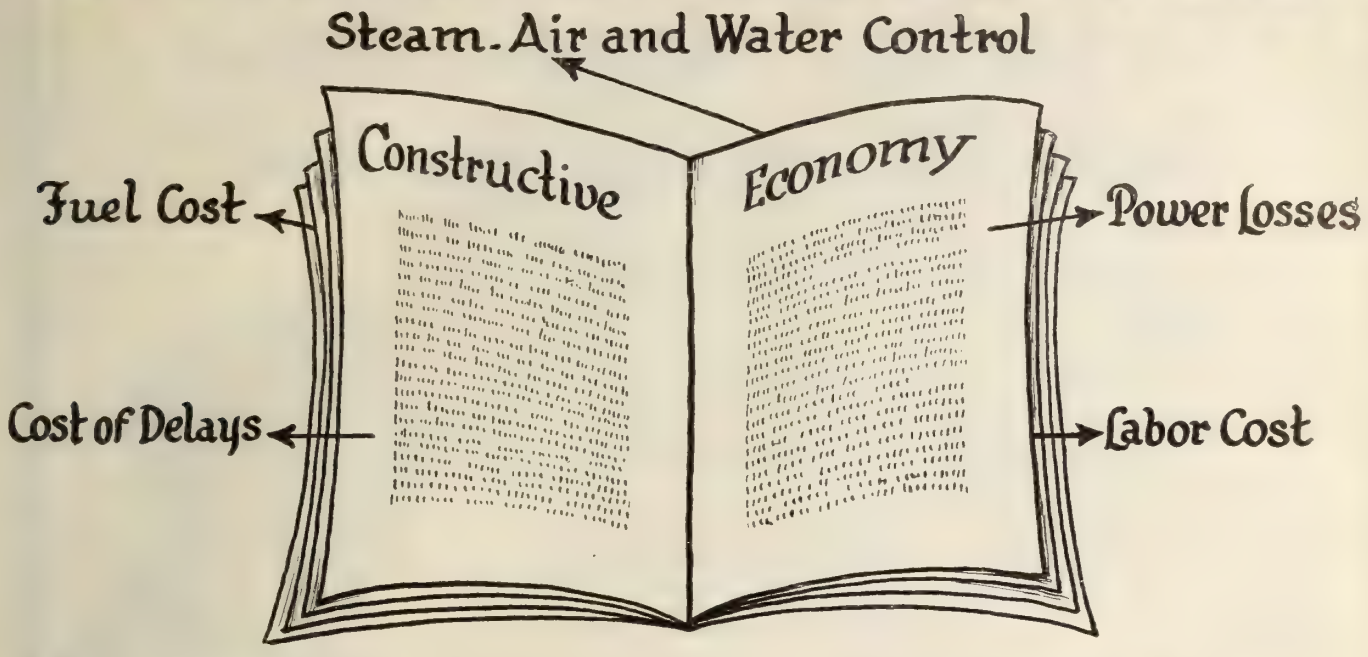
LOOK FOR THE NAME ON THE NUT



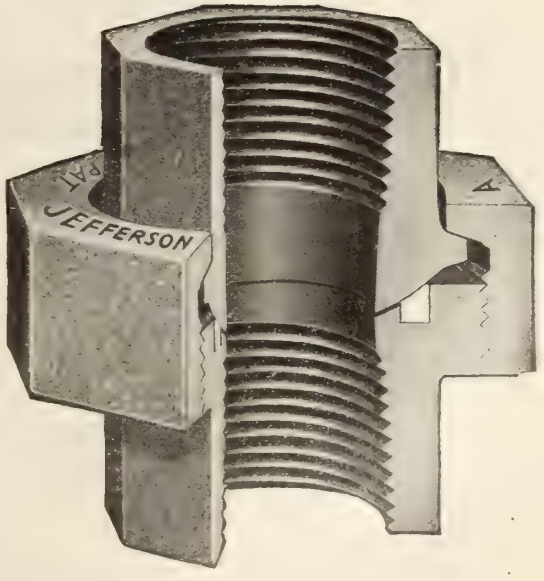
Are there any Leaks in your Policy of Constructive Economy?

JEFFERSON UNIONS will help you tighten up. Every connecting link in production must be capable of meeting the straining demands of the times if the present power plant slogan, "Economy and Efficiency," is to be other than a meaningless one.

From the most expensive machine down to the seemingly insignificant piping details **dependability** must be the embodiment of every individual factor. Each succeeding step from the source of power to the output must hold steadfast in its functioning, for weakness in any one of the connecting units may nullify the good results of the whole system.

The little union in the pipe line is an important big thing.

When the unions are JEFFERSONS, **dependability** is added to importance, for they assure absolutely tight joints in the pipe lines.



The Jefferson Union provides joints that will not corrode, loosen, dislodge or leak. It is made of the best high-grade air-refined iron, well proportioned and unusually strong. It has a ground ball brass to iron joint, a drawn brass tubing seat and perfect machined-like threads.

Ask your dealer about Jeffersons—the full line of ELBOWS, TEES and FLANGES. Our Catalog sent on request.

JEFFERSON UNIONS

Do You Get Real Lasting Service From The Packing You Use?

Or are you using one of those packings that are made to effect frequent sales?

There are packings and packings, many of which are sold only on price and require renewing so often as to be really expensive in the end, especially the labor cost of renewing the packing, which is the largest item of expense.

The engineer who uses a packing that gives long service under the peculiar conditions of his plant not only saves money for the owners, but avoids a lot of hard, unnecessary labor for himself.

Our claim for

TRADE MARK
"PALMETTO" PACKING
REG U S PAT OFFICE

is that it is a packing with only one object in view — LONG SERVICE.

We can prove to you that "PALMETTO" will outlast the packing you are using if you will let us send you—without charge —working samples to test under your own conditions in your own way.

Write us at once, stating the size you wish.

Cleanliness Easily Maintained in ELESCO SUPERHEATERS

The long life of Elesco Superheater units is due to the prevention of scale and the maintenance of clean surfaces. This cleanliness is obtained by providing for high steam velocities which prevent the accumulation of scale-forming material in the superheater.

Cleanliness is further obtained in Elesco Superheaters because the units present smooth, easily cleaned gas touched surfaces.

Insure Constant Level

The most economic way to operate boilers is with constant water level and uniform constant inflow. With the level held constant at middle gage, the greatest amount of heating surface is presented to the hot gases and the maximum amount of steam space is available.

Vigilant Feed Water Regulators

meet these conditions in a very satisfactory way.

They are easily adjusted to maintain an absolutely constant water level at any arbitrarily determined height in boilers, and they feed continuously with perfect uniformity.

Better Belting with Efficiency "Built In"

Efficiency is a result—in our belting it is the culmination of thousands of experiments and tests over a period of fifty years.

The outstanding factor in creating transmission efficiency in our Dominion Friction Surface Belting is our special friction rubber compound which gives our belts a pulley-gripping quality that prevents practically all wastage of power through slippage.

Dominion Friction Surface Belting

will transmit all the power that any belt can be made to transmit because every ounce of material is carefully tested by our experts to make sure that it is up to our high standard.

This "Built-in Efficiency" is backed by the service of our belting engineers, who are ready to demonstrate its value without charge or obligation.

Lubricating Oil Specifications and the De Laval Oil Purifier

Thousands of dollars are spent each year for experiments and tests which determine the most satisfactory and economical lubricant for various power units.

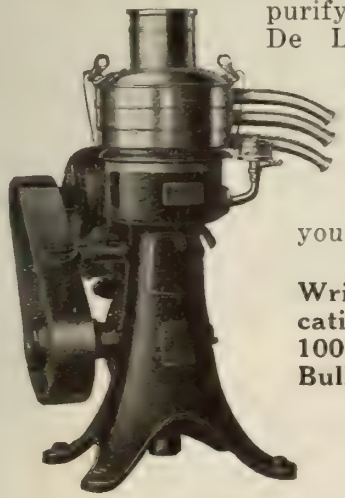
In some cases the time and money so spent is practically wasted by continuing the use of the oil after it has become foul.

Dirt, grit, water and particles of metal are at times present in every lubricating system—sometimes to such an extent as to cause the oil to act as an abrasive rather than a lubricant.

The De Laval Oil Purifier removes these impurities from used oil and maintains its original lubricating qualities.

The useful life of the oil is prolonged with a consequent saving in oil bills; the danger of burned-out bearings is largely eliminated, and the oiling system is less likely to become clogged.

Many of the largest power plants have replaced older and less efficient methods of purifying used oil with De Laval Centrifugal Purifiers. The experience of the De Laval engineers who designed these installations is yours for the asking.



Write for Oil Purification Bulletin No. 100; also Crank Case Bulletin No. 102.

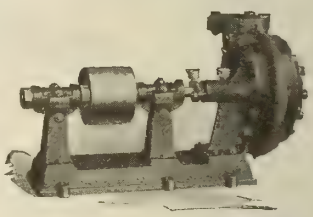
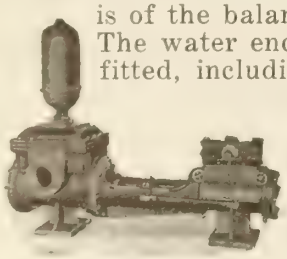
AMERICAN-MARSH PUMPS

SIMPLE RELIABLE EFFICIENT

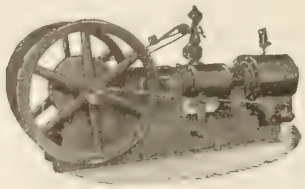
The American-Marsh steam pump is an improved form of the famous Marsh Pump which has been on the market for over thirty years, during which time over 150,000 have been manufactured and sold.



The American-Marsh Pump has no internal stuffing boxes, no tappets and no slide valves. The auxiliary valve is of the semi-rotative disc type of an improved design. The main steam valve is of the balanced piston pattern, assuring highest efficiency. The water ends have large valve areas and are fully bronze fitted, including solid bronze piston rods and bronze removable water cylinder bushings.



American-Marsh Centrifugal pumps are made with the same high grade of material and workmanship which characterizes the construction of the steam pumps. They are made in all sizes up to 12 inch, both single and two stage for heads up to 250 feet.



The line also includes—
Power Pumps
Deep Well Engines
Air Compressors
Jet Condensers
Dry Vacuum Pumps
Boiler Feed Pumps

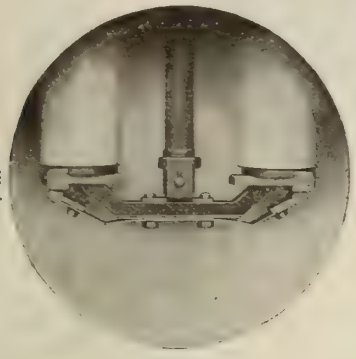
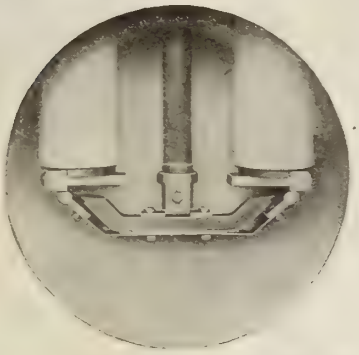
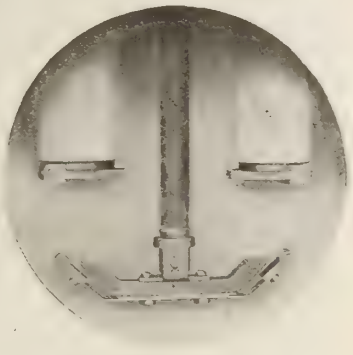
FOUR CONDIT FACTS



1—Closed



2—Arcing Tips Protecting Brush



3—Open

Condit Oil Switch Construction

1. Note the perfect wiping contact of the Condit main laminated brush contacts, closed.

2. The circuit is broken by the auxiliary arcing tips. No arcing from main contacts.

3. Liberal Clearance when switch is fully opened.

4. Condit Type D-13 Oil Switch with individual Tank-per-Pole arrangement, providing high factor of safety.

¶ Condit D-13 Oil Switch has a maximum capacity of

300 amperes at.....27,000 volts
500 amperes at.....25,000 volts
and
800 amperes at.....15,000 volts

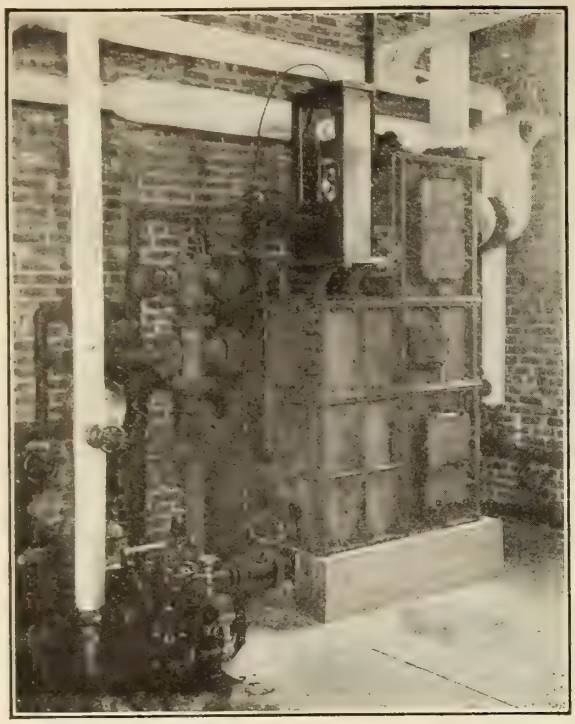
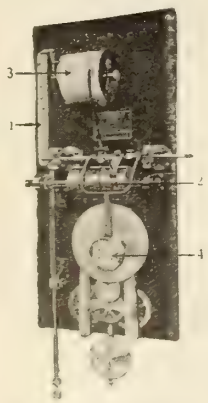
4—Condit Type D-13 Oil Switch



98.5% Accurate at All Times

The value of any metering device is dependent upon the accuracy of the recording instrument itself. And it is not enough for the instrument to be accurate at the time of its installation; it must retain this accuracy under all conditions of service and for a length of time measured in years.



The Yarway-Lea Recorder automatically furnishes four kinds of information:
1. Inches head of flow falling over weir.
2. Instantaneous indication of rate of flow.
3. Graphic paper record in pounds or gallons of liquid during any part of 24 hours.
4. Total volume or weight of flow over any period between two readings.

Sturdiness of construction and simplicity of operation enable the Yarway-Lea V-Notch Recorder to maintain its accuracy of within one and one-half per cent. for an indefinitely long period. In no case has this instrument ever depreciated in accuracy, even after many years of service.

The illustration shows a Yarway-Lea V-Notch Recorder used in conjunction with a feed-water heater-meter at the plant of the Sinclair Consolidated Oil Company, Trembley Point, N.J.

The Yarway-Lea Recorder is the only genuine Lea Recorder made and sold in this country. Booklet L-40 contains complete details. Shall we send you a copy?

Yarnall-Waring Company

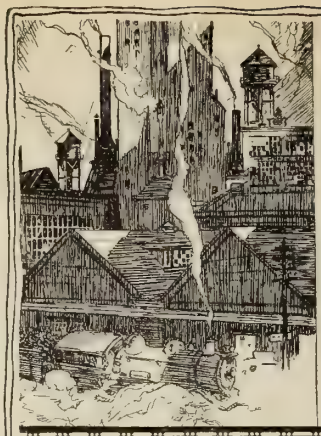
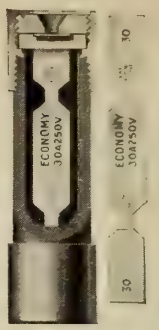
Offices in all Principal Cities

Yarway Products are being used in thousands of plants. They are sold under a money-back guarantee.





Ferrule Type, Economy Fuse with Economy "Drop Out" Renewal Link.

ECONOMY *renewable* FUSES

Progressive industries using electrical energy obtain more dependable protection to lives, property and machinery—at less cost—when they discard "one time" fuse equipment for

Economy renewable Fuses

The famous Economy "Drop Out" renewal link cuts annual fuse maintenance costs 80%.

Knife Blade Type Economy Fuse

It is the least expensive and the only portion destroyed when an Economy Fuse blows.

Economy "Drop Out" Renewal Links invariably operate at rated capacity. They are inexpensive—a reserved stock kept always on hand represents but a small investment.

The Fuse itself—fibre cartridge, end caps and the winged washer which locks the link securely in place—is used again and again.

The merits of Economy Fuses have been recognized officially, for they were the first line using inexpensive bare renewal links for restoring blown fuses to their original efficiency to be approved in all capacities by the Underwriters' Laboratories.

Your plant needs Economy Fuses.

For sale by all leading electrical jobbers and dealers.

"In the Smugglers' Den"

An Intimate and Dramatic Story of Boot-leggers and the Activities of Rev. J. O. L. Spracklin of the Border Cities.

MR. CHARLES CHRISTOPHER JENKINS, the writer of this story, arrived in Windsor a few hours before Trumble was shot by the Rev. J. O. L. Spracklin; and during the next few days among the experiences which befell MacLean's Magazine special representative was one of particularly dramatic and timely interest —a few hours spent within the lair of one of the smugglers' "Master Minds." This graphic story from Mr. Jenkins' pen will enable you to get a real grip of what this all means, particularly from the side of those who are beyond the pale of the law.

The story is illustrated by some exclusive and timely photographs showing the chief actors and various resorts within the sphere of their activities.

December 1st Issue of MACLEAN'S Brimful of Fascinating Reading

"AUTOBIOGRAPHY OF MRS. ASQUITH"
Wife of the former Prime Minister of Great Britain.
One of the strongest and most interesting stories Mrs. Asquith tells in her extraordinary reminiscences.

"THE CITY OF PERIL"
By Arthur Stringer.
Four more pages of this gripping, enthralling, melodramatic story of Bolshevistic adventure in New York.

"JEFF HEARS THE CALL"
By C. W. Stephens.
The story of a fight with forest fire, of rescue by the air route from a horrible death by flames.

"LINKING TWO INLAND SEAS"
By J. L. Rutledge.
Here you have the account of the struggles which led to the construction of one of Canada's greatest transportation links.

"THE TEST"
By Harry C. Douglas.
This is a charming little short story with a surprising conclusion.

"THE DRAMA OF OUR GREAT FORESTS"
By Arthur Heming.
The second instalment of this gripping serial is entitled "Oo-Koo-Hoo's Eldorado." On the cover will be another Heming picture.

"FLIRTING WITH OUIJA"
By Col. George H. Ham.
The genial George's adventures in the mystic, with necromancers and hypnotists.

"LEAVES OF KACHUBOONG"
By Madge Macbeth.
An intriguing detective story by the well-known Canadian authoress, who has specialized in depicting criminal types.

"FIRST ROW, ORCHESTRA"
By Leslie G. Barnard.
In this you have the catchy story of a small town girl who became a big town actress.

"OUR GOLDEN FLOOD ROARS EAST"
By Nicholas North.
The story of how our grain is graded; the difficulties in marketing 275,000,000 bushels of wheat.

Review of Reviews

Some of the subjects treated in our reviews in December 1st issue include :

Fiume under d'Annunzio.
The War Spirit in the World—Sisley Huddleston.
Russia in the Shadow—H. G. Wells.
Benedict XV, Royal Diplomat.
The Irresistible Thing—Sir Gilbert Parker.
The Russian Intelligence—Leo Pasvolsky.
Simple Solution of the Labor Problem.
Letting the Prisoners Govern Themselves—Frank Tannenbaum.
German Universities Hard Up—Allen W. Porterfield.
The New Search for Oldest Man—Roy C. Andrews.

COPPUS TURBO BLOWERS EFFECT STEADY SAVINGS

In the modern plant of the New York Ice Company, New York City, this 22" COPPUS Turbo Blower has been saving time, money and labor ever since installation in April, 1917. It has **made possible** the use of cheap fuel, and **made sure** the maintenance of constant steam pressure. So satisfactory has been the service of this COPPUS Blower that two more blowers have since been purchased for other plants of the New York Ice Company.

COPPUS Turbo Blowers are cutting down fuel costs and keeping up steam pressures in old storage and artificial ice plants all over the country. Automatically regulated, self-oiling, quiet running, COPPUS Turbo Blowers are by far the most efficient means of securing mechanical draft.

Let our engineers tell you just what COPPUS Blowers can save you in your boiler room. Write for Blower Catalog.

Used the World Over

The value of Green's Economisers as fuel savers is proven daily all over the world. In Europe, South America, Japan and China—wherever steam is generated by stationary boilers, especially in the great industrial centres, there you will find

GREEN'S ECONOMISERS

The Green's Economiser installation in Chelsea Station, London, England, is the largest of its kind in the world—about 15,000 tubes. Though of such recognized efficiency as to be chosen for installations of this size, its fuel conserving value is equally as great in the small plant. Let us tell you just how Green's Fuel Economisers will save you 10 to 15 per cent. on your coal bill, **no matter what the size of your plant!**

GREEN'S ECONOMISER, LTD.
TORONTO

Our engineers will be glad to submit data showing the saving possible to you by installing economisers.

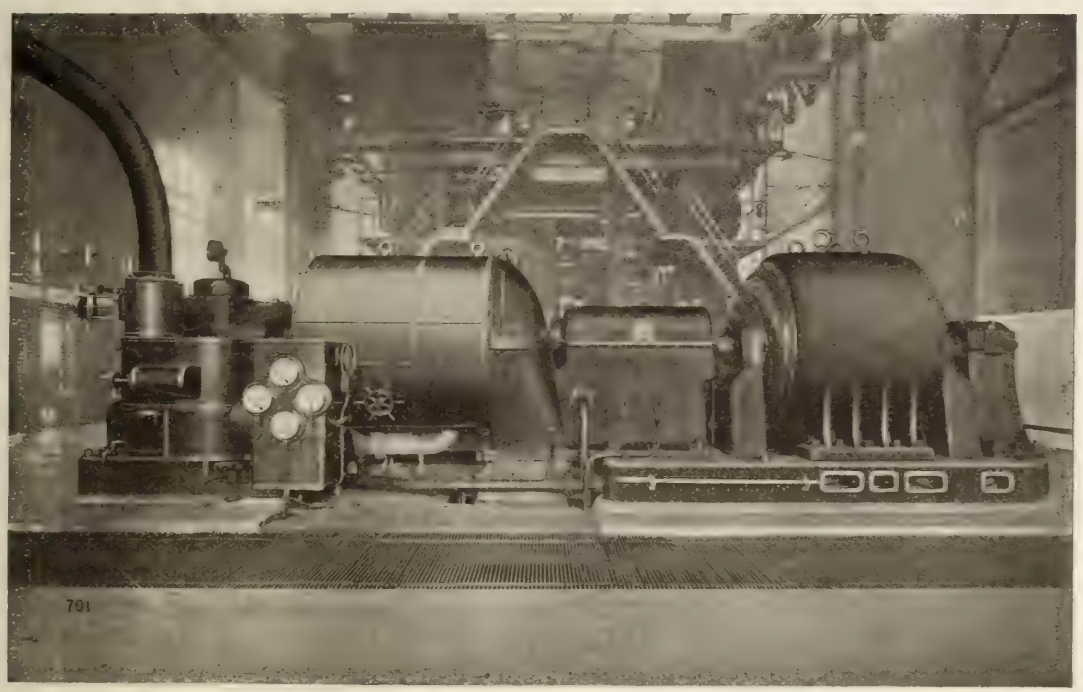
BELLISS & MORCOM
LIMITED

Engines and Air Compressors

The engineers who purchase equipment for the large engine rooms are invariably keen buyers.

It is a notable fact that Belliss & Morcom Engines and Air Compressors are to be found in many of Canada's largest engine rooms.



Belliss & Morcom 2000 K.W. Steam Turbine at Montreal Tramways Power Plant

High-Grade Power Equipment

Steam Engines	Air Compressors	Pressure Filters
Gas Engines	Condensing Plants	Gravity Filters
Oil Engines	Centrifugal Pumps	Water Softening Plants
Diesel Engines	Boiler Feed Pumps	Refuse Destructors
Steam Turbines	Water Meters

Rigidly Tested

NORWALK AIR & GAS COMPRESSORS

You are sure when you purchase a Norwalk Compressor that the machine will arrive in condition to give the specified results as soon as it is properly set up and connected to power.

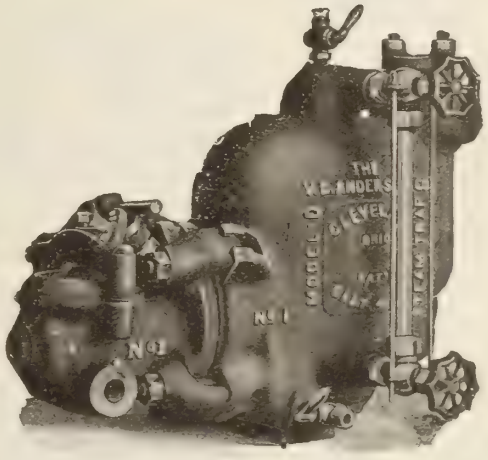
Every Norwalk Compressor is rigidly tested in all details before it leaves our plant. Nothing is left to chance or experiment at your end of the line. This characteristic Norwalk thoroughness saves you time, bother and money.

One or all of the Norwalk Bulletins on compressors for air, oxygen, hydrogen, acetylene and carbonic acid gas will be sent on request.

The Norwalk Iron Works Co.
Pioneer Builders of Compressors
SOUTH NORWALK, CONN.

Canadian Sales Representative
A. S. Leitch Company, Toronto

ANDERSON
Model "D"
Steam Trap



Steam Condensation is Impossible

IT is impossible for any condensation to gather with this trap. Three inches of water seals the valve and seat, so when condensation is exhausted no steam is allowed to escape.

The Anderson Model "D" Steam Trap gives efficient and economical service. It automatically drains the condensation from radiators, steam coils or heating systems without reducing pressure or permitting the escape of live steam.

The Anderson, by reason of its interchangeable parts, can be used on any steam apparatus where there is condensation to handle. Its sturdy construction and simple design are unequalled.

If you are troubled with condensation problems, get our catalogue—a post card brings it.

COAL IS KING
Wire screens are laid on standard laboratory tripods. A beaker of water is placed directly on the screen at the left. Before placing beaker at right, ⅛ inch of soot is spread over the screen.
Produced and loaned by FORD MOTOR CO.
COAL IS KING
At end of two minutes. Water is boiling in beaker at left—while the temperature of the water in the second beaker is only 120 degrees, due to poorer transmission of heat on account of soot.
Produced and loaned by FORD MOTOR CO.

Laboratory Tests Point the Way to Greater Boiler Efficiency

What The Moving Pictures Show

SCENE: Chemical Laboratory of Ford Motor Co.

OCCASION: Production of motion picture, "Coal is King." (This film deals with all phases of coal conservation in the boiler-room. It has been shown before several hundred American engineering societies.)

ACTION: Test to illustrate the bad effects of soot in preventing heat transference when allowed to accumulate on boiler tubes.

RESULTS: The pictures tell the story—water is boiling in the beaker with clean surface exposed to flame, whereas it has only reached a temperature of 120 degrees in the beaker with soot insulated surface.

When soot accumulates on the heating surface of a boiler the result is identical with that obtaining with the soot insulated beaker. A large part of the heat is lost because it is not transmitted to the water. This means excessively high coal bills, and poor, uncertain service from the boiler. Obviously high efficiency in the generation of steam is dependent upon the maintenance of the cleanest of clean heating surface.

In thousands of boiler-rooms "Cleanliness" and "Diamond Soot Blowers" are synonymous terms. Diamond Soot Blowers clean large portions of the boiler which cannot be reached by the hand lance, and clean those which can be so reached, better. As compared to the best possible results by hand cleaning, Diamond Soot Blowers will—save 4% to 8% fuel—increase overall boiler efficiency—and decrease labor required in the boiler-room.

At present fuel prices Diamonds will completely pay for themselves in four to six or eight months. If 100 to 200 per cent. dividends per year from an investment in your boiler-room would interest you, write for Bulletin 280.

Connelly Water Tube Boilers (Patented U.S. & Canada)

are of the 4-drum type; have 100% tube area in the path of circulation, and deliver steam superheated to from 5 degrees to 10 degrees Fahrenheit. Simple in design, no flat surfaces, no stay bolts, no crown bars, no braces, no hand-holes, free from joints.

All parts easily accessible for cleaning, both internally and externally. Can be built in units from 200 H.P. up to 4,000 H.P. and 300 lbs. pressure. 150,000 H.P. in successful operation.

Stephen Leacock and Agnes C. Laut have been added to the list of regular contributors to your Magazine—MacLean's. These writers need no introduction to Canadian readers. Watch coming issues of MacLean's Magazine.

We have something else to bring to your attention again—the attached statement of your subscription account. May we ask you to favor us with your remittance, thus showing tangible appreciation of a Canadian periodical we ar e trying to make increasingly worthy of your subscription.

We certainly do not like to worry you about this unnecessarily, nor do we allow these items to worry us to the extent of interfering with the service we give you. Wouldn't it be a matter of mutual satisfaction though to have this straightened out?

I sometimes wonder what happens to letters and accounts that we send to some of our friends. May I respectfully suggest that you give this matter the attention you think it deserves—NOW—before you again forget about it?

Every reader in your home derives pleasure and profit from every issue. Remember that $5 will pay your subscription for 3 years.

A return envelope is enclosed and we await an early receipt of your favor.

Yours very truly,

THE MACLEAN PUBLISHING CO., LTD.

DIRECT CONNECTED WORTHINGTON
"FEATHER" VALVE AIR COMPRESSOR

"FEATHER" Valve

(REG. U. S. PAT. OFF.)

insures machine efficiency

AS MR. NAT EMERSON, of the Standard Carbonic Co., writes to his Cincinnati office concerning the original "FEATHER" Valve equipment in the first "FEATHER" Valve Compressor turned out by Worthington. "... These have been in service about five years and two months and you will note are still in good shape."

"This Compressor, as you know, has been very satisfactory and was instrumental in selling a similar one to the Peabody Hotel of this city, and several to the I. C. shops here in Memphis."

All Worthington Gas and Air Compressors, Snow type Oil and Gas Engines and the mammoth Worthington All American designed Marine Oil Engine are "FEATHER" Valve equipped—very pertinent reason why Worthington apparatus has proved so successfully efficient.

Other Worthington Products:
Steam, Power, Centrifugal and Water Works Pumps Meters, Oil Engines, Condensing Machinery, Air Compressors, Vacuum Pumps and Water Wheels.

To further enlarge their service, Worthington have acquired the good-will and mechanical equipment of the Platt Iron Works, Dayton, Ohio, for manufacturing Oil Mill Machinery, Hydraulic Turbines, Feedwater Heaters and High Pressure Air Compressors.

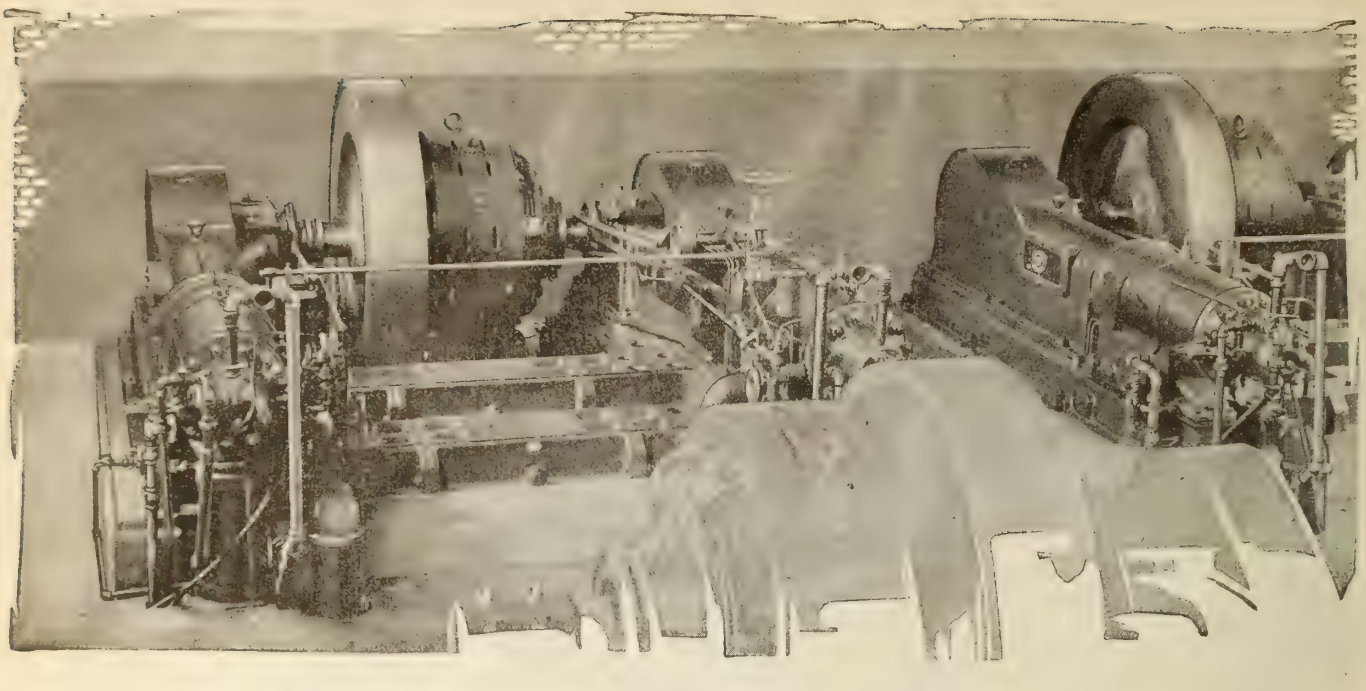
POWER HOUSE, December 20, 1920. Vol. XIII., No. 24. Published semi-monthly at 143-153 University Ave., Toronto, Canada. Subscription price in Canada, $2; in United States, $2.50. Entered as second-class matter at the Post Office Department, Ottawa, Canada. Entered as second-class matter July 1, 1912, at the Post Office at Buffalo, under the Act of March 3rd, 1879.



Where standby power became steady power

WHEN you employ a man and he makes good, you want to keep him.

Same way with engines. These Giant Semi-Diesel Oil Engines were put on the job and made good as a standby power. Now they're *regulars.*

Only an engine of Giant dependability could burn low-grade fuel oils, and supply steady power unfailingly. But Giant ruggedness withstands the test of severe service. It operates with day-in and day-out certainty, with negligible upkeep costs.

Scarcity of expert attendants does not concern Giant users. Due to an unusual simplicity of construction and operation it takes little time to start, superintend and stop the engine. No valves, carburetors, costly auxiliaries, or other complicated mechanisms to become inoperative. Result—low attendant costs; low upkeep expense; absolute dependability.

Giants will make good on low-grade fuel oils in *your* plant. Bulletin upon request.

Poor Lubrication is Costly

PLANT operators insist upon efficient, scientific lubrication these days. They realize that poor oil is expensive at *any* price.

Imperial Lubricants are especially prepared to meet the modern demand for correct lubrication. There's a grade of uniform-quality oil for each different lubrication requirement of your plant. Supplies are always conveniently available.

Hundreds of firms all over Canada use Imperial Lubricants exclusively. Actual records show a marked reduction in overhead expense and increased capacity throughout plants where Imperial Lubricants are regularly used.

You cannot afford to buy any but the best oils for expensive machinery. Check over the accompanying list of Imperial Lubricants. See how fully it meets every lubricating need.

Imperial Engineers will gladly help you standardize the lubrication of your plant. Write to 56 Church St., Toronto.

Dependable Draft

No mechanical stoker can be more dependable than its source of air supply. Both its efficiency and flexibility in carrying high boiler ratings, depend directly upon the ability of its forced draft equipment to deliver the proper amount of air at the right pressure.

Sturtevant
(TRADE MARK)

Forced Draft Apparatus

—covers every possible requirement from a small undergrate turbo blower to the most powerful types of forced draft turbine fans.

Designed and built by the pioneers in the field and the largest manufacturers of mechanical draft equipment.

Installed in the largest central stations in this country and abroad. Your special draft requirements will receive the consideration of our specially trained fan engineers who will recommend the most economical apparatus for your work.

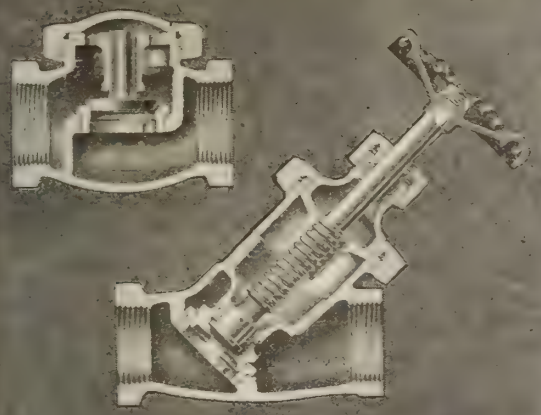
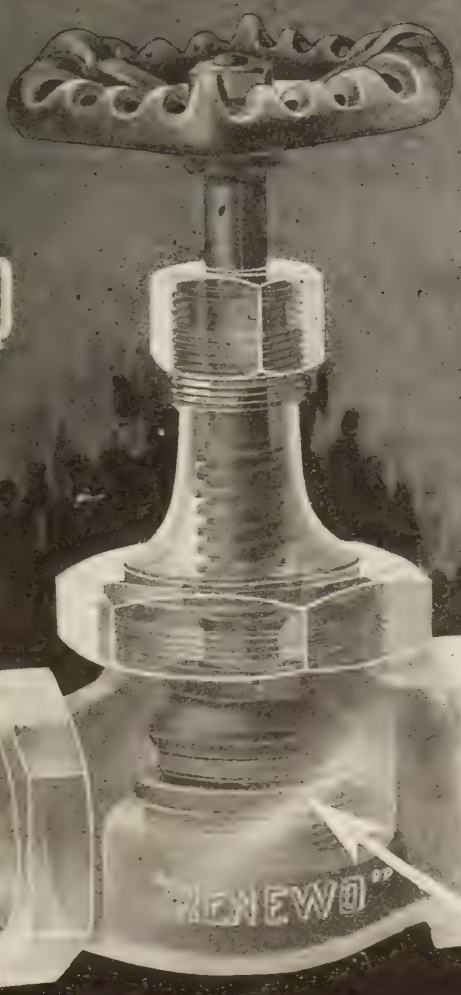
LUNKENHEIMER "RENEWO" VALVES





Have achieved an enviable record for economy in steam service. They represent the highest development in valve construction, incorporating all the good features discovered and developed in over half a century of valve manufacture.

Their installation means permanence in the line, because they are as near wear proof as can be attained, and to further enhance their durability all the parts are interchangeable and can be replaced should necessity require.

"Renewo" Valve parts are made of materials best suited to the duty the part performs.

The *Renewable Seat* and *Disc* are made of Lunkenheimer "Valve-nickel," a material having exceptional wear-resisting qualities; the Disc is provided with the celebrated Lunkenheimer "Seat-guard" which aids in preserving the seating faces and keeping them clean, and the seating surfaces are regrindable. The stem is made of a special bronze; the thread is extra long and has full contact when valve is opened or closed.

The union bonnet connection with outside protected threads; deep stuffing box with gland follower, and the self-cooling malleable iron handwheel are other points of merit.

Globe, Angle, Cross, Straightway or Y and Horizontal and Angle Check Patterns for 200 and 300 pounds working steam pressures. Specify LUNKENHEIMER "RENEWO" and insist on having the genuine.

A Merry Christmas

TO Our Friends one and all we extend the compliments of the season. May the New Year be one of Prosperity and Success to you all.

FOR your patronage in the past we thank you. May we look for its continuance in the future, and we shall endeavor, as we have done in the past, to show our appreciation by giving you the best service within our power.

Let us resolve to make the coming year one remarkable for larger undertakings and greater accomplishments that Canada may grow in greatness and power.

The Safe and Certain Boiler Cleanser

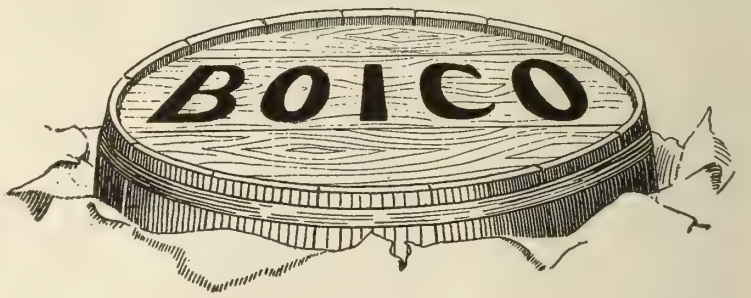
PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.**

BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.



Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

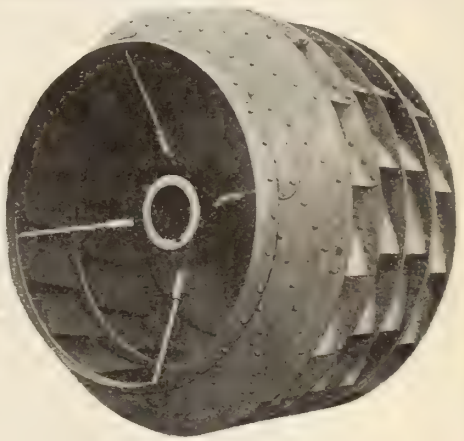
GREEN'S

HI-EFFICIENCY HI-SPEED

RADIAL FLOW FANS



Economical, Sturdy, Efficient

Green's Radial Flow Fans are possessed of many advantages. They require approximately 20% less horse power than any other fans. Are so designed that the rotor and bearings are easily accessible without changing the alignment or dismantling the flue work. Any blow back through the fan inlet or dead space on the fan wheel is impossible due to the design of rotor and housing. They run at speeds best suited for direct connection to turbines or motors and are also suitable for gear or belt drive.

Consult our engineers. They will gladly furnish you complete information with regard to fans to cover your individual requirements.

UNEVEN PRESSURE MADE CONSTANT

A varying pressure in your supply line can't impair the working efficiency of any apparatus requiring a constant pressure—with the TAG Self-Operating Pressure Controller straddling the motive power and doggedly gripping the pre-determined pressure.

Day in and day out, **constant pressure is automatically maintained**—without any other attention of the engineer to the controller than to "set it and forget it."

What a difference between this simple, economical method that really controls the pressure, and the old wasteful, time-consuming way of juggling the hand valve, which only approximates the desired pressure!

Put a TAG Controller on the pressure line—immediately, uneven pressure is made constant.

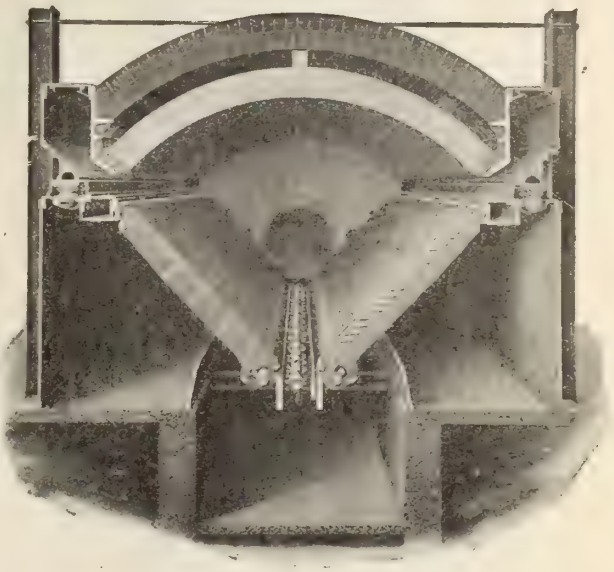
MURPHY AUTOMATIC FURNACES



WHEN COAL WAS CHEAP —AND NOW

The Murphy Furnace earned its way forty years ago when coal was "dirt cheap." Think how much more quickly it can pay for itself when it saves 15 to 25 per cent. of the price you pay for coal to-day!

Murphy Furnaces bring to the smaller plant the economical advantages of the larger plant without resorting to forced draft, so the money you save on auxiliary equipment goes far toward paying for their installation.

Under present conditions it is economy to equip even the smaller boilers with Murphy Furnaces—for it saves your fuel and enables you to burn the poorer grades of coal that everyone gets these days.

If your boilers are 50 H.P. or larger you should get in touch with us. Send for Catalog HM-12 and see how easily the Murphy Furnace can be installed under any type of boiler.

Carrying Higher Peak Loads Without Adding New Equipment

The peak load capacity of boiler plants may be considerably increased by making it possible for all the heat generated in the furnaces to be used in making steam when there is a sudden increase in demand. To do this, the rate of flow of boiler feed water must be temporarily cut down when there is a sudden increase in load. Otherwise the raising of feed water to the boiling point inside the boiler uses up a considerable portion of the heat generated by the furnace. To carry maximum peak load, all the heat the furnace can possibly generate should be directed towards the generation of steam alone.

Bulletin D tells all about how this is accomplished by the

NONPAREIL GRATES

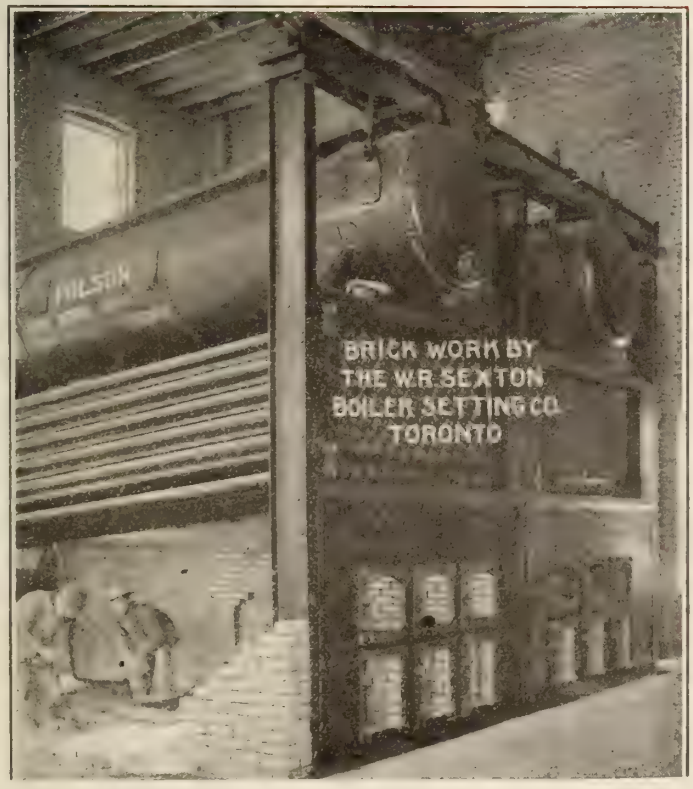
The Enemy of High Fuel Prices

When big manufacturing firms install new equipment they never jump at conclusions or take anybody's word as to its merits. They have their own experts investigate first. This is exactly the course taken by the following well-known firms before installing NONPAREIL SHAKING AND DUMPING GRATES:

The Deloro Smelting & Refining Co.

The International Nickel Co. of Can. Ltd., Two Sets

The Brunswick-Balke-Callender Co. of Can.



Before any of these companies installed NONPAREIL GRATES they satisfied themselves of their efficiency and economy—that they would give perfect combustion, improved service and would SAVE FUEL, and otherwise live up to the claims we make for them. When firms like these place their stamp of approval on Nonpareil Shaking and Dumping Grates, they must surely possess advantages.

Attractive Trial Offer

You are at liberty to order a set of NONPAREIL GRATES and test them out FREE of charge. We guarantee a saving of at least 10 per cent. on your fuel consumption. This is fair and reasonable—why hesitate?

Firebrick Work

Some of the largest power plants in Ontario have had their Firebrick work done by "Safety First" Sexton and his staff. Quality work only! Remember, Nonpareil Grates and Sexton's Brick Work make an unbeatable combination.

REPAIRS—Grate Bars supplied, and repairs made to all kinds of Shaking and Dumping Grates.

To Our Readers, Contributors and Advertisers

IT is with genuine pleasure that we take this opportunity of extending to all our friends, who are included in the above, the very heartiest and most sincere good wishes for a bright and happy Christmas, and a New Year full of prosperity and joy.

The end of a year is a time for both retrospect and foresight. We look back over the year gone by with satisfaction, feeling that it has been a year of good effort, and definite results. We look forward to the coming year as a period wherein the works of the past year will be supplemented, and advanced. We fully expect to see our circle of readers extended, more and more influential contributors attracted, and more advertisers taking advantage of the opportunity "Power House" affords them of getting in touch with the people who need and buy their wares.

To do this it is necessary that we, on our side, continue to give the service in both editorial and advertising pages, which we have endeavoured to give during the year gone by. It has been a source of pleasure to see the number of requests for advice that have come in during the year, all of which have been promptly answered, both by personal letter and through the columns of "Power House." We have been also the pleased recipients of many grateful letters from correspondents who have benefited by the advice given in this way.

There is another way in which we serve both our readers and advertisers which is not apparent on the surface. We allude to the not inconsiderable amount of advertising which we refuse, for articles which we do not believe to be genuine, and unable to live up to the claims made for them. Like quack medical nostrums these articles deceive the people who purchase them, and lower the tone of the paper that advertises them, and "Power House" will not accept such advertising.

Editorial plans for the coming year look to giving our readers the highest class of engineering information available. A feature which has met with great favor, our "Course of Instruction," will be continued, and will cover, as stated, all the work for the Ontario examinations The number of expressions of approval this course has received has been a great encouragement, and we feel we are supplying a very urgent demand.

Here's hoping that all those engineers who cannot get away from their duties on Christmas Day will have their turn on New Year's Day. We hope this time next year to address all our old friends, and a whole horde of new ones, so we will leave you all to enjoy the festivities of the season, with the time honored

Merry Christmas and a Happy New Year

A Series of Articles on Power Plant Management

In This Article the Author Discusses the Principle of the Steam Turbine and Its Advantages. The Application of the Turbine, And the Use of High Vacuum are Noted.

By ROBERT JUNE

THE past decade has witnessed a remarkable development of the steam turbine. This development has taken place not only with respect to the design of turbines, but in particular with respect to the very great increase in their application to different services.

Among the classes of work for which steam turbines are now being utilized, addition to the driving of alternating rent generators, are the propulsion of pumps, blowers, turbo-compressors and marine propellers. By means of gearing they are used to furnish power for reciprocating air compressors, rolling mill drives and other classes of slow speed machinery. At every point the steam turbine has found favor on account of its low first cost, low maintenance cost, small floor space requirements, and low cost of attendance. It is, indeed, making appreciable progress in relegating the reciprocating steam engine to a secondary and minor position. Although the reciprocating engine will be an important factor in power plant work for some time to come, its field is being rapidly narrowed.

The Principle of the Steam Turbine

Under given pressure and temperature conditions a pound of steam occupies a known volume and contains a definite amount of heat energy. Now, if our pound of steam is permitted to expand to a lower pressure without receiving additional heat or giving up heat to surrounding bodies, it is capable of doing a certain amount of work which will be the same whether the expansion takes place in the cylinder of a reciprocating steam engine, a rotary piston engine, or the nozzles and blades of a steam turbine.

The process of expansion of the steam in the turbine differs from that in the reciprocating engine in that the flow of steam is continuous instead of intermittent. The steam turbine is a continuous mechanism, whereas the reciprocating engine may be termed a ratchet mechanism. The reciprocating engine is designed to operate by the direct pressure of the steam, while the turbine is designed to work by changing the direction of motion of the flowing steam. The turbine is thus, in fact, a velocity motor and the steam engine a pressure motor.

The kinetic energy of fluid in motion is the source of power in the steam turbine. Let a fluid in motion impinge on moving vanes, change the direction of flow and reduce the velocity of the fluid, and the energy of the fluid will be converted into mechanical work and become available throught the shaft on which the moving vanes are placed.

The successful steam turbine must embody the following characteristics:

1. The highest possible percentage of the heat energy of the steam must be converted into kinetic energy.

2. Provision must be made to utilize this kinetic energy in the most efficient manner by proper design of the rotor, nozzles and guide passages of the turbine.

3. Design and construction of casing, rotor, and blades, must be such that they will hold their form and remain tight against leakage under heat and centrifugal strains.

4. The velocity of all moving parts must be within safe limits and the apparatus must run at the proper speed at point of delivery of power.

Advantages of the Steam Turbine

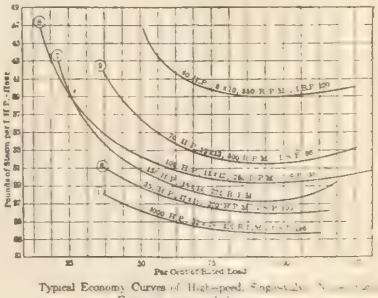
Among the principal advantages of the steam turbine are:

1. First Cost.—As a general proposition steam turbines are lower in first cost than reciprocating engines of equivalent rated capacity. In a general discussion of this character, little would be gained by reciting specific examples to prove this proposition. This is true because of the various uses to which turbines are applied and on account of the extreme variations in design. However, it is safe to say that for general service conditions it will be found that the turbine is lower in first cost than the steam engine in four cases out of five. The way to determine the matter in a specific case is to get actual figures from builders of both reciprocating engines and of turbines.

2. Maintenance and Attendance.—The reciprocating engine contains a much smaller number of parts than the turbine, but on the other hand, the turbine possesses a very great advantage over the other type of prime mover because of fewer moving parts and rubbing surfaces. The only contact between the moving and stationary parts is in the main bearings, and the problem of lubrication is, therefore, a simple one. Furthermore, the absence of pistons, stuffing boxes, dash pots, and friction surfaces reduces the cost of maintenance and attendance to a minimum and limits the possibility of leaking.

3. Economy of Space and Foundation.—Reciprocating engines require much greater floor space than do steam turbines. As compared to a Corliss compound engine, a turbine of equivalent size will only take up from one-third to one-half the space. With straight line, non-condensing, high-speed engines the comparative economy in space is much less marked. However, even in such cases the average space occupied by the turbine is from twenty to fifty per cent. less than that of the engine.

A most important feature of the steam turbine is that it is very much lighter in weight than the reciprocating engine. In the case of central stations, engines and generators may weigh as much as eight times more than turbine installations of equal capacity. Even in



Typical Economy Curves of High-speed, Engines

smaller installations the turbine is very much lighter than the engine, and also because of a total absence of vibration requires a relatively light foundation. In many cases turbine foundations consist simply of steel beams with concrete arches, so that the basement underneath may be used for the condenser and other apparatus instead of being devoted to the massive foundation required for reciprocating engines.

4. Absence of Oil in Condensed Steam.—Requiring as the turbine does no internal lubrication, there is no opportunity for oil to come in contact with the steam. Consequently, all steam from the surface condensers can be used for boiler feeding purposes without purification. This continued use of condensate effects a large saving in cost of feed water and in expense for maintenance and initial cleaning of boilers. Furthermore, the amount of entrained air is reduced to a minimum, and, consequently, the work of air pumps is lessened.

5. Regulation.—It is much easier to regulate the speed of the turbine within close limits than it is a reciprocating engine. With the latter, moreover, a heavy fly-wheel is required to keep the instantaneous angular fluctuation within safe limits. Even with a constant load there are variations of velocity during each revolution of the reciprocating engine, while with the steam turbine the speed is practically constant. A number of published tests of Parsons and Curtis turbines show an average fluctuation of not more than two per cent. from no to full load, and of not more than three per cent. from no load to one hundred per cent. overload.

6. Overload Capacity.—When we come to discuss overload in a prime mover we are at some disadvantage because of the fact that the rated load usually refers to the maximum economical load or the point of greatest efficiency. Both engines and turbines should, of course, be designed with the operating conditions clearly in mind, so that they will operate at all times at high economy. The point of superiority of the turbine over the reciprocating engine lies in the fact that when occasion arises it can be operated with a greater percentage of load above the point of high efficiency than can the reciprocating engine.

Comparative Economy of Steam Engines and Turbines

Any attempt at a specific comparison of the steam consumption per brake horse power of reciprocating engines and steam turbines is very unsatisfactory because of the wide range of operating conditions.

As a general proposition the reciprocating engine is more economical in the use of steam for non-condensing service and the contrary is true for high pressure, high vacuum, condensing service.

The general statement we have just made should be modified so far as it concerns condensing engines of the uniflow or poppet valve type as these engines, under favorable conditions, often show superior economy to the turbine for sizes up to 3,000 horse-power. The superiority of the uniflow and poppet valve engines over the ordinary slide valve type lies in the fact that their construction is such that the steam is not brought into contact with cold surfaces to the same extent.

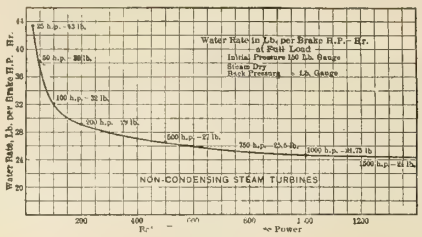


FIGURE 2.

A comparison of the curves in Fig. 1 showing typical economies of high speed, single valve, non-condensing engines, and the curves in Fig. 2 showing the performance of non-condensing steam turbines is somewhat in favor of the reciprocating engine, the difference decreasing as the size of the unit increases. When we come to make a similar comparison on the performance curves of compound, single valve; single cylinder, four valve; and compound, four valve, non-condensing, reciprocating engines with those of steam turbines of the same size we find a marked increase in economy in favor of the reciprocating engine.

In order to give some definite idea of the steam consumption of the small turbine we include Table I, which gives the manufacturer's guarantee on one of the best known makes:

Performance of the Modern Steam Turbine at Rated Capacity.—(Manufacturer's Guarantee).

Rated Capacity	R.P.M.	Initial Pressure, Lb. Abs.	Back Pressure, Inches.	Superheat, Deg. Fahr.	Lb. Steam Per Kw-hr.	Rankine Cycle, Ratio.
25 H.p.	3600	165	At.	0	*43.0	*31.0
50 "	3600	165	At.	0	*38.0	*34.2
100 "	3600	165	At.	0	*32.0	*40.6
200 "	3600	165	At.	0	*29.0	*44.9
500 "	3600	165	At.	0	*27.0	*48.1
750 "	3600	165	At.	0	*25.5	*51.0
1,000 "	3600	165	At.	0	*24.75	*57.5
1,500 "	3600	165	At.	0	*24.0	*59.1

*Based on developed horsepower.

A very interesting combination plant which has frequently been used in this country consists of a high pressure engine exhausting into a low pressure condensing turbine. This arrangement is very hard to beat so far as economy is concerned.

It should be kept in mind, however, that there are a great many other factors besides high economy to take into account in deciding whether to purchase a turbine or a reciprocating engine. Every one of the factors mentioned earlier in our discussion under advantages of the steam turbine should be given consideration, and it is quite possible that they will be found to outweigh the advantage of high economy of the engine.

When plant conditions make it practicable to provide super-heated steam for turbines without incurring more than a normal expenditure, it is desirable to do so. The gain in heat economy due to the use of super-heat is theoretically the same for all types of prime movers. Actually, however, the rate of improvement varies considerably with the type of mechanism. In the reciprocating engine the gain is due mainly to the reduction of cylinder condensation, while in the turbine the improvement in economy is due primarily to the reduction in "windage" and other friction losses. The actual gain is, furthermore, very much greater than the theoretical gain. In the ideal frictionless high pressure condensing turbine an increase of 35 degrees in superheat would effect an increase of about one per cent in thermal efficiency. In the actual turbine we gain 1 per cent. increase in thermal efficiency for each 6 to 14 degrees that we increase the superheat.

Superheat is of greater advantage with non-condensing units than with condensing turbines, and it is more marked with low pressure units than with high. In average practice the maximum temperature of the steam is approximately 500 degrees F., but in large central stations, temperatures of 600 degrees are not uncommon, and a number of recent installations have been designed for total temperatures of 700 degrees F. It should be remembered that the higher the initial temperature, the greater will be the investment cost and that a point will eventually be reached where the increased fixed charges will affect the gain in heat economy.

Influence of High Pressure

In planning new installations it is extremely important to bear in mind the fact that the higher the steam pressure, the higher the economy. As a matter of fact, the increase in efficiency resulting from high boiler pressure is so marked that engineers are considering the possibility of employing pressures far above any now in use. We now have plants designed and in use where the boiler pressure is 350 pounds, and when it is possible to do so, working temperatures of 600 pounds per square inch will be employed.

There is no particular obstacle so far

as the turbine is concerned in the use of such high pressures since it simply means the use of heavier parts for the high pressure end and a somewhat increased cost of construction. The difficulty lies with the boiler construction, and just when or how the problem will be solved, is still a matter of uncertainty.

Installations at the extremely high pressuring just mentioned are and will be chiefly confined to the big central stations. However, it is well to keep the desirability of high pressure in mind in designing a new small plant. In other words, do not assume that a pressure of 150 or 175 pounds is about right, without giving the matter further consideration. It may prove just as easy, far more economical, to use a working pressure of 250 or 275 pounds.

The Influence of high Vacuum

High vacuum can be used to much greater advantage with the steam turbine than with the reciprocating engine. Even if it were practical to expand the steam to one pound absolute, the increased condensation in the reciprocating engine would probably render any gain due to expansion useless. A study of a number of tests of reciprocating engines shows but a slight improvement in overall plant economy due to increased vacuum beyond 26 inches. A test of steam turbines shows a decrease in steam consumption of about 5 per cent. for each inch of vacuum between 25 and 27 inches, six per cent. for the gain between 27 and 28 inches, and eight to twelve per cent for the gain between 28 and 29 inches. These values are approximate only, since the influence of vacuum on steam consumption varies greatly with the type and size of turbine.

Here again we must remember that there is a critical point beyond which it is not economical to go in securing high vacuum. As the volume in steam increases very rapidly with the decrease in back pressure, the corresponding capacity and power required by the air and circulating pumps becomes proportionately larger. There is consequently a point where the improvement in steam economy fails to exceed the increased power demanded by the auxiliaries.

Turbines vs. Engines in Units of Small Capacity

The question of whether to use reciprocating engine or turbine is frequently a puzzling one to the owner of small plants. Some years ago Mr. K. S. Barstow presented a complete summary before the A. S. M. E. covering the applicability of engines and turbines for plants of less than 500 horsepower capacity. In studying this summary it is well to remember that considerable improvements in the turbine and its range of applicability have been made in the past several years, and that it is possible to use turbines in at least some of the applications assigned by M. Barstow to engines.

Applicability of Engines

1. Non-condensing units, direct - connected or belted and used for driving:

Electric generators of all classes excepting exciter sets of small capacity, unless belted from the main engine. Centrifugal pumping machinery, operating under variable head and quality conditions and at relatively low heads, say up to 100 ft., depending on the capacity of the unit. Pumps and compressors for delivering water or gases in relatively small quantities and at relatively high pressures in the case of pumps at pressures above 100 lb. per square inch and in the came of compressors at pressures from 1 lb. per square inch and above.

Fans and blowers (including induced draft fans) for handling air in variable quantities and at relatively low pressures, say not over 5 in. water column.

Line shaft of mills, where the driven apparatus is closely grouped and the load factor is good.

All apparatus requiring reversal in direction of rotation, as in hoisting engines and engines for traction purposes.

2. Condensing units direct-connected or belted, for all the above purposes particularly where the condensing water supply is limited, and where the water must be recooled and recirculated.

Applicability of Turbines

1. Direct-connected units, operating condensing. 60 cycle generators in all sizes, also 25 cycle generators above 1,000-k.w. capacity.

Direct-current generators in sizes up to 1,000-kw.. capacity, including exciter units of all sizes.

Centrifugal pumping machinery operating under substantially constant head and quantity conditions, at at moderately high head, say from 100 ft. up, depending upon the size of the unit.

Fans and blowers for delivering air at pressures fromb 1½ in. water column to 30 lb. per square inch.

2. Direct-connected units, operating non-condensing for all the above purposes, in these cases wherein steam economy is not the prime factor or where the exhaust steam can be completely utilized, and, in the latter case, particularly where oil-free exhaust steam is desirable or essential.

3. Geared units, operating either condensing or non-condensing for all the above-mentioned applications, and in addition, many others which would otherwise fall in the category of the steam engine, on account of the relatively slow speed of the apparatus to be driven.

Next month we will discuss the individual types of turbines and deal with some of the problems incurred in their operation.

COLLINGWOOD CO. GETS THE CONTRACT

And Work at Dominion Shipbuilding Plant Will Be Carried On In a Few Days

The plant of the Dominion Shipbuilding Company at Toronto, which has been idle since the company went into liquidation some time ago, is to be operated again for at least five or six months. The liquidator, Mr. Osler Wade, announced that at a conference with the Minister of Marine and Fisheries, Hon. Mr. Ballantyne, arrangements had been completed for the finishing of work upon the two Dominion Government ships in the yards. The work will be taken over by the Collingwood Shipbuilding Company, which will employ about a thousand men. Places will be found for a large percentage of the old staff and wherever possible preference will be given to returned men. The two vessels are of 4,000 tons each and it is estimated that they will provide employment for a large number of men on into the spring or early summer.

Mr. Wade stated that he would make no attempt to sell the plant at present and that any offer made for it, during the completion of the two ships, would be subject to the arrangement made with the Minister.

OTTAWA LODGE HOLDS OPEN MEETING

Ottawa Lodge No. 6, C.A.S.E., held an open meeting in their hall on Thursday evening, November 25th, which had a very large attendance. The principal feature of the evening was a lantern lecture given by Bro. C. V. Clarke, manager for Darling Bros., Ltd., Ottawa Branch, subject being "Steam specialties and their application to the modern steam plant."

One of the views shown was a typical layout showing a method of using exhaust steam for heating purposes, etc. Consequent views showed various steam specialties in detail incorporated in the typical layout.

Br. Clarke also demonstrated the use of special apparatus for the operation of modern radiator traps and explained their construction.

The demonstration was made with a "Webster" syphon trap and a "Webster" No. 7 trap.

This open meeting and lecture was the means of adding three new members to the order.

Ottawa Lodge intends to hold a series of open meetings during the winter. It is also planning a drive to increase the membership of the C.A.S.E. in Ottawa.

Chas. Berry, President.

R. E. Rodney, Recording Secretary.

The Welding of Locomotive Fireboxes

Full Welded Fireboxes, Semi-Welded Fireboxes, Semi-Welded Half Side Sheets, and Full-Welded Half Side Sheets Are Taken Up in This, the First Part, of Complete Article on Above Subject.

Compiled by J. H. M.

IT IS not often that one is able to state in concise form the experience of two experts, but in the article to follow, dealing with the welding of locomotive boilers, the data contained therein have been gathered by Messrs. Geo. L. Walker and R. T. Peabody, both of the air reduction engineering service department of L'Air Liquide Society. This matter was placed before those interested in book form by L'Air Liquide Society, and through their courtesy the author is now able to compile this material in the form best suited for our purpose.

The oxy-acetylene process has stepped very much to the fore in late years, and has proven of great value in the repairing of fire boxes and flue sheets, principally because the joints are perfectly water-tight, while the speed with which the work can be accomplished adds still more to its value.

Failures have been recorded in the past but these have been traced to incorrect methods employed. This has been largely owing to inexperience on the part of the workman, or even utter lack of knowledge of the conditions. No one can make a success of welding until they become acquainted with the principles involved, choosing suitable apparatus, supplies, and so on.

General Instructions

The information to follow is given chiefly to assist the practical welder who might be or is working on locomotive boilers, and who is ambitious enough to read about what others are doing in that line. The methods advocated constitute the standard practices adopted by many railroad shops on this continent, and if carefully observed will ensure satisfactory results.

In the preparation of the work for welding, to ensure success it is necessary to observe five important things: First—The cleanliness of the sheets at welding seam. Second—That sheets are bevelled at a proper angle. Third—That sheets are in correct position. Fourth—That provision is made for expansion and contraction, and fifth—that you have suitable welding rods as filling material.

Before cutting a new patch, carefully inspect part to be welded and cut out all defective places, then cut only where there is a good foundation for the weld. When cutting out patches, carefully avoid cutting through stay bolts if possible. Do not under any circumstances cut out sheets or patches through old welds. For side sheets or three-quarter door sheets, extend new sheets at least one stay bolt higher; for crown sheet, one stay bolt lower; for patches, extend weld at least one row of stay bolts larger; for flue sheets, extend weld to one row of stay bolts lower.

When cutting out sheets or patches with cutting torch, cut them straight and bevel afterwards—preferably with a chisel. Clean surfaces are essential to good welding. Scale, rust, oil or grease must not be allowed to remain on the part to be welded, otherwise satisfactory welds are impossible. The most satisfactory angle for bevelling plates is an angle of 45 deg., making between the two plates an angle of 90 deg., or a right angle. All sheets and patches must fit with an opening of from ⅛ in. to 3-16 in. between patch and sheet all around—never less than ⅛ in. and never more than 3-16 in.

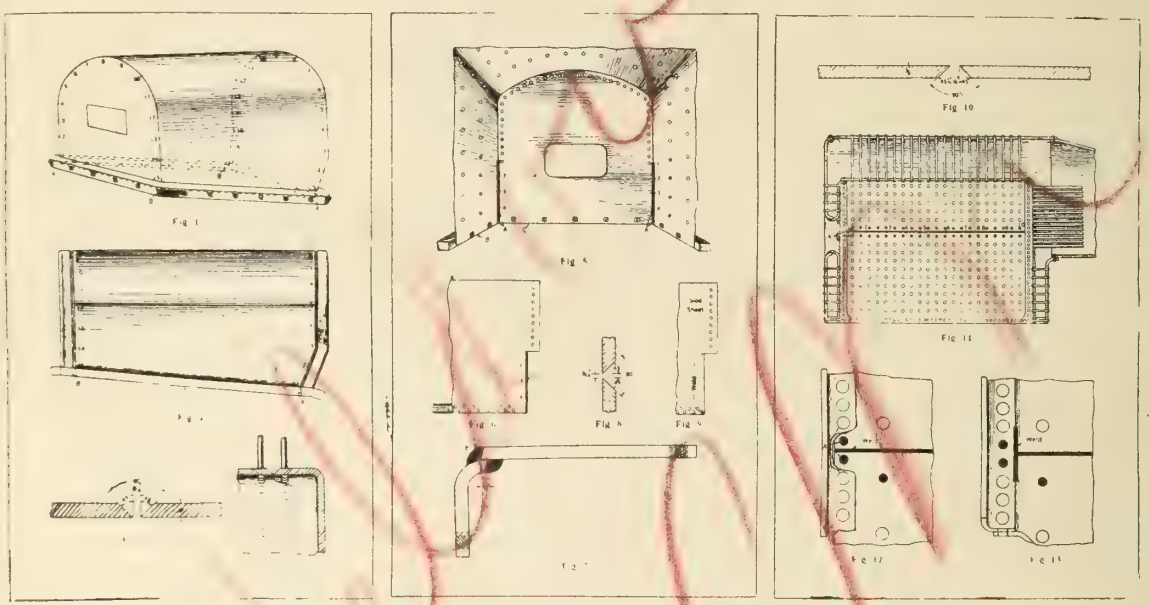
The welding of cracks in side sheets, door sheets, fire doors, crown sheets, bottom and top of flue sheets should not be attempted, or only resorted to in cases **of extreme emergency, to be corrected at the very first opportunity.** Welding cracks in barrel of boiler, welding over stay bolts and welding stay bolts is not allowed under any circumstances.

Welding of Full-Welded Fireboxes

A full-welded firebox is one which has all of its joints welded instead of riveted. The welded joint, to the investigator's opinion, is stronger, more economical, will not leak, and has more durable expansion and contraction properties than the riveted seam. The welding should be performed as follows:

First place the firebox upon the mudring A B A B, Fig. 1, and bolt it fast. Next, prepare to weld the outside, or water side, of say the flanged flue sheet to the firebox, as shown at Fig. 2, by cutting a bevel of about 45 degrees all the way along its edge from mudring to mudring. Now bevel the matched edge of the firebox in like manner. The best practice is to make the flange of the flue and door sheets so as to include a row of radial staybolts. See Fig. 4.

After this set the firebox so that the weld joint remains open at its bottom



FIGS. 1 TO 13. INCLUSIVE.—TEXT DEALS FULLY WITH THESE EXAMPLES.

about 3-16 in., Fig. 3, allow for expansion, to clinch the welding metal and insure a perfect weld through the vee. Start the joint by welding it for about an inch just above the mudring, say at 1, Fig. 1, using 3-16 in. or ¼ in. Swedish iron welding rod, and a good welding blowpipe with suitable tip. From a point about 10 in. up from the mudring weld downward from 2 to 1. Then, continuing the method, weld from 3 to 2, from 4 to 3, and so on. This practice will prevent the spreading of the joint from unequal expansion. Add enough welding rod to raise the surface of the weld about ⅛ in. above the original metal. If practicable, a second welder should follow the outside welder and smooth-flow the joint on the inside while it is red hot. This will be certain to make the joint tight.

Working from the inside, weld the firebox to the mudring at the corners A and B, Fig. 1, then weld on the door sheet the same as the flue sheet.

Welding Semi-Welded Fireboxes

A semi-welded firebox is one on which welding is substituted for riveting along the lower vertical joints of the flue and door sheet with the side sheets. This practice is followed where it is desired to avoid riveted joints in the fire zone, and some shops also weld the bottom horizontal joint of the firebox and the mudring for about 12 inches both ways from each corner. The chief advantage of this welding is the elimination of leakage. The work should be done as follows:

First bolt the firebox to the mudring and rivet the flue and door sheets to the side sheets down to within about 36 inches from the mudring. Omit the rivet holes along the corner joints to be welded from 1 to A, see Fig. 5. Also leave out temporarily the rivets next to the top of the joint at 1, Fig. 5.

Next prepare the side sheets as shown in Figs. 6 and 9, but cutting into the flange about ⅝ in. so that it can be set down flush. Butt the joints and bevel both edges at about 45 degrees on the outside of the firebox. Leave a 3-16 in. opening at the bottom of the vee as shown. Some welders have used a lap weld like that shown at Fig. 7, but it does not make as strong and tight a joint. The butt weld as shown at Fig. 8 is the best for such work.

The next step is to tack-weld the flange at 1, see Fig. 5. Use a good welding blow-pipe for this purpose, making sure you have a suitable tip, and a good grade of welding rod.

Starting on the outside at about 10 inches below 1, weld from 2 to 1. Then from 3 to 2, and 4 to 3. Complete the joint by welding on the inside from A to 4. Weld the other three corners in like manner. If a second welder is available the metal should be flowed on the inside while being made.

Welding of Semi-Welded Half Side Sheets

Semi-welded half side sheets are those which are welded along the horizontal joints to the crown sheets, and are riveted to the mudring at the bottom and to the door and flue sheets at the ends. The welding of the long seams should proceed as follows where the door and flue sheets have not yet been set.

First proceed to bevel the edge of the half side sheets and the corresponding edge of the crown sheet as shown at Fig. 10. Next screw in the second row of staybolts and bolt the sheet to the mudring before starting to weld. To avoid delay, all of the staybolts, except the rows adjacent to the weld may be screwed in and set, and the side sheets riveted to the mudring before the welding is done.

On this being completed, weld about 2 inches of the joint at 1, Fig. 11, then, beginning at 2, about 10 inches from 1, weld back to 1, from 3 to 2, and so on to the end of the joint. Use a good welding blowpipe, with suitable tip, and as before, make sure a good grade of welding rod is used. The door and flue sheets should now be riveted in.

If the side sheets are to be put in after the door and flue sheets have been set, the flanges of the door and flue sheet should be heated and raised as shown at Fig. 12. This will allow the part of the joint under the flange to be bevelled.

When the new door and flue sheets are put on, the adjacent rivets A, see Fig. 12, should be left out until the welding is completed.

In Fig. 13 is shown the practice of welding the end of the long seam when it is desired to change an old riveted joint to a welded one. The vertical weld should be carried to the second rivet each way.

Full-Welded Half Side Sheet

A full-welded half side sheet has no riveted joints at the top or sides, all three edges being welded. The work should be performed as follows: Cut out the flange of the door or flue sheet next to the joint of the crown and half side sheets, as shown at A and D, Fig. 14. Then bevel the flange, including rivet hole C, and set it flush with the half side sheet. Next bevel the crown sheet, including the rivet hole B. Now set the side sheet so that a ¼ in. space is left at its top and sides, and then bevel those edges. If this sheet is not riveted to the mudring, bolt it fast. Screw in and set all staybolts except those next to the welds.

Now weld the horizontal seam for about 1 in. at 1, as shown at Fig. 15. Then from point 2, about 10 in. from 1, weld back to 1, and from 3 to 2, continuing until the joint is completed. Next start about 10 inches down the vertical joint of, say, the door sheet at 10L and weld up to 1, see Fig. 15. Then from 10 inches below 10L and 11L weld back to 10L, from 12L to 11L, and so on to within a few inches of the mudring.

Weld the flue sheet joint the same way as the door sheet, from 10R to 9, see Fig. 15, from 11R to 10R down nearly to the mudring. Weld the bottom of the joints to the mudring at 15L and 15R last. When the flanged joints of the door and flue sheets are in good condition, but the rest of the plate needs renewing, a good job may be performed by setting in the half side sheet, as shown in Fig. 16. It should be tacked at 1. Then weld from 2 to 1, 3 to 2, and so on, following the practice described above.

Welding Cracks In Side Sheets

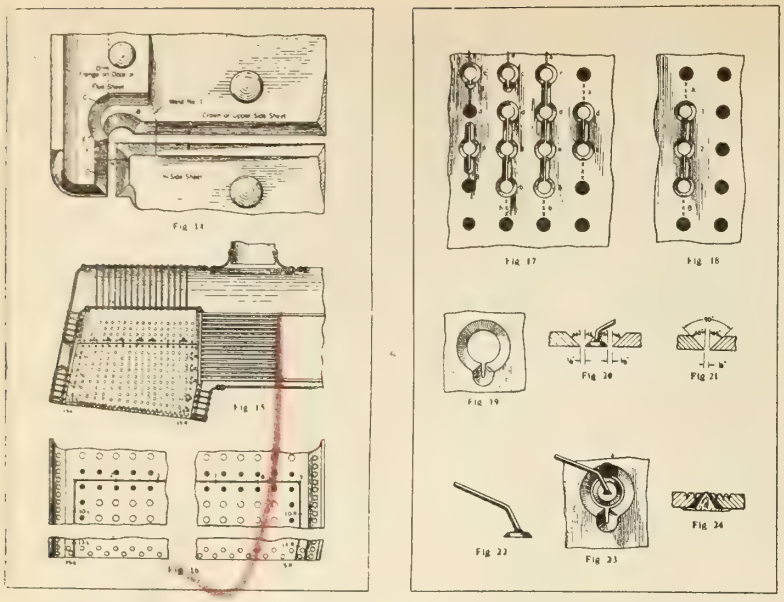
Cracks in side sheets between staybolt holes are not easily welded, because of the difficulty of making proper allowances for expansion of the metal. In fact, if a side sheet has many cracks like those shown in Fig. 17 it would be better to put in a new sheet rather than resort to welding. Much welding of side sheets is being done, however, and the following method may be successfully used when the staybolt holes are to be closed:

To weld a crack like that at Fig. 18, bevel the sides of the hole and crack, as shown in Fig. 19. Prepare for each hole a soft steel disc about 3-16 in. thick and of say ¼ in. smaller diameter than the hole. Bevel the edges of the disc, as shown in Figs. 20 and 21. Melt a piece of welding rod to the disc to serve as a holder, hot-bending the rod, as shown in Fig. 22.

Next place the disc in the hole and melt down the upper edge a, see Fig. 23, to tack the disc in position. Preheat the metal between the two holes at xxxA, Fig. 18, and keep it red hot. Melt off the rod and complete the welding of the disc into the hole. Now allow the hot section xxxA to cool with the weld at 1. This provides for uniform shrinkage. Weld hole 2, Fig. 18, in the same way, and then weld the crack from 2 to 1.

PREPARING WORK

To secure a successful weld, you must first prepare the work properly. There are five important things to observe, viz., the cleanliness of the sheets at the welding seam, that the sheets are bevelled at proper angle, that they are in correct position, that provision is made for expansion and contraction, and that you have suitable welding rods for filling material.



FIGS. 14 TO 24.—FURTHER EXAMPLES. SEE TEXT FOR DESCRIPTION.

Preheat the section xxxB when welding the last hole of that line. The weld should be reinforced, as shown in Fig. 24.

In some cases where it is not practicable to replace a badly cracked side sheet by a new one, or put on a patch, the welding may be done as follows: Referring to Fig. 17, preheat the top of the left row of holes at xxxa. Then weld in hole c of this row. Preheat the area xxx down to d, as well as that at xB. Weld the crack at the bottom of the hole e of the first row, then the staybolt hole e, the crack at the top of this hole, and finally weld the joint around the head of the staybolt d, which is assumed to be in good condition. Reheat the area xxxa to relieve the shrinkage strains, and let the job cool down before proceeding with the other rows.

Weld the last row on the right next by preheating at xxxa, filling the holes at d and e, and then the crack between them. Reheat the lower part of the row at xxx, and allow the whole job to cool uniformly. Now weld the second row from the left in the usual way, and allow the sheet to cool again. Weld the third row from the left last, which is done in this case because it is the longest continuous crack.

THE ADVANTAGES OF REDUCED GRATE AREA

By W. H. Casmey

In the burning of coal the average maximum percenatge of CO_2 is 19.2 per cent. With 1 pound of coal and 12 pounds of air, the CO_2 is 19.2 per cent., and the furnace temperature 3844 deg. Fahr. As this temperature is too high for steam-raising purposes, the practice by which the author has secured the best results is to allow 50 per cent. excess of air to the products of combustion, the resulting temperature being 2630 deg., and the CO_2 13 per cent. If, then, the CO_2 indicator forms, as it should do, a part of every steam plant, the economical conditions are as easily maintained, other things being equal, as the height of the water in the boilers by means of the pump and gauge glasses.

In everyday practice the percentage of CO_2 seldom exceeds 7 per cent., and taking this figure and the same quality of coal as before—i.e., 12,000 B.t.u. per pound, 7 per cent. CO_2 means 33 pounds of air per pound of coal, the furnace temperature being 1510 deg., or 1120 deg. lower, due to having 15 pounds more excess air per pound of coal.

We have abundant proof that an over-all efficiency of 75 to 80 per cent. is possible—in fact, is now being secured—but in comparison there are thousands of boiler plants to-day giving less than 60 per cent., and one battery of ten boilers tested by the author gave an over-all efficiency of only 53 per cent., including boilers and economizers.

During the last few years many old boilers have been fitted with parallel flues; two of such, 8 ft. in diameter, are now in the yard of the author's firm, the flues 3 ft. 8 in. diameter, or 2 inches less at the front end than in the modern boiler of same diameter, and 4 inches larger in diameter at the back end; but this old type will evaporate 15 per cent. more water per hour than one of modern design under exactly the same conditions. To prove this statement, let us assume that each boiler was operated by a suction equal to 1200 ft. per minute at the rear end; the old boiler offers 14 sq. ft. to this suction, the modern boiler 11.2 sq. ft.; the old boiler has an air supply sufficient to burn 1116 pound of coal per hour, and, taking 8 pound of water per pound of coal, gives an hourly evaporation of 8928 pounds. The modern boiler has only air supply for burning 942 pounds of coal, and at the same rate of evaporation per pound of coal the hourly duty will be 7536 pounds, from which it is clear that six Lancashire boilers, as made one hundred years ago, will evaporate as much water as seven boilers of the same diameter of present-day type. This is not progress.

From the above it is clear a relationship exists between the grate area of a boiler and the area through which its gases escape, and in the old type the ratio is 2.57 to 1, and in the modern boiler of equal diameter 3.5 to 1, the respective evaporations per square foot of grate being 248 and 197 pounds.

In our Lancashire boilers as made today—standard length 30 ft., diameter ranging from 7 ft. to 9 ft. and upwards, grates 6 ft. long, and furnace flues contracted at the rear end 6 in.—the practical results under such conditions are that a boiler 7 ft. diameter requires 4 sq. ft. of grate to evaporate as much water as can be done with a 9 ft. diameter boiler with 2.7 sq. ft. If boilers 7 ft., 8 ft., and 9 ft. diameters were worked with equal draught, the respective evaporations per square foot of grate would be 144, 184, and 238 pounds, but if the grates were modified until the ratio of grate to outlet was 2 to 1 in each boiler the evaporations in all three would be equal to, say, 312 pound per square foot of grate. The whole subject of modified grates is explained in the author's booklet on coal economy recently published by Charles Griffin and Company, London, and specially written for firemen and enginemen.

"We backed the wrong horse in taking on the boiler of 1873 with contracted flues instead of holding on to the straight-flued boiler of 1811, but we cannot now, without great expense, increase the diameter of our present boiler flues at the back and secure the 2 to 1 ratio; we can, however, secure it by merely reducing the area of our furnaces and share in the value of the idea, as the following extracts from letters received indicates others are doing:

(a) "We have four Lancashire boilers 30 ft. by 8 ft., fitted with coking stokers and induced draught; we have cut down our firegrates from 6 ft. to 3 ft. 10 in., and reduced our coal consumption over 700 tons per year."

(b) "Our plant consists of two Lancashire boilers, 30 ft. by 9 ft., fitted with sprinkling stokers; length of grates 3 ft. 6 in., with a dead plate behind the bars 2 ft. 6 in. long. Our engines develop 800 h.p.; class of fuel, rough slack; evaporation per pound of slack, 9 pound."

(c) "We have one Lancashire boiler, 30 ft. by 8 ft., and by cutting down the grates from 6 ft. to 4 ft. we have reduced our coal consumption 140 tons per year."

(d) "Since cutting down our boiler grates one-third we have saved 10 per cent. in fuel and stopped black smoke."

(e) "Since reducing the grates in our 28 ft. by 7 ft. 6 in. Lancashire boilers from 6 ft. to 3 ft. 9 in. eighteen months ago, we have reduced our coal consumption two tons per week."

(f) "In the author's own works the grates of the 30 ft. by 8 ft. boiler have been reduced one-third, and the saving effected exceeds one ton of coal per week."

The Utilization of Waste Heat Under Boilers*

The Various Methods of Applying Waste Heat Under the Furnaces of Boilers Are Discussed, and a Direct Fired Unit is Compared to a Waste Heat Boiler Unit.

By D. S. JACOBS and A. D. PRATT

IN the earlier practice with waste heat boilers it was the custom to minimize the frictional resistance of the gases flowing through the boiler by providing a large flow space, in order to interfere as little as possible with the draft leaving the industrial furnace, such as a copper smelting furnace which supplied the waste heat. This practice limited the field of application of waste heat boilers. To show the progress in the art we will deal with the modern practice of our own particular company, in which a boiler is provided having a high draft resistance and in which the baffling is arranged to give a relatively small area of flow space through the passes so as greatly to increase the velocity of the gases. A suction fan is used to overcome the higher draft loss due to the increase in velocity of the gases, and the heating surface of the boiler is arranged in series in such a manner that in connection with the added draft loss under the increased velocity the desired draft will be afforded at the outlet of the furnace supplying the waste heat as well as at the outlet of the boiler.

The total capacity of waste heat boilers, built in accordance with our modern design, which we have installed during the past seven or eight years in various classes of waste heat work is over 150,000 rated horse-power. The capacity these boilers are developing in terms of normal rating varies, of course, with gas weights and temperatures. A conservative figure would be 70 per cent. of normal rating, which is on a basis of ten square feet per horse-power, which would mean a total of 105,000 horse-power actually developed. In the ordinary plant where waste heat installations are made, the coal burned in direct fired boilers of various types, averaging the poor results with the good, will in all probability be at least four pounds per hour per horse-power developed. On the basis of 105,000 horse-power developed, four pounds of coal per hour per horse-power, 24 hours' operation, 300 days a year, the total annual saving in coal alone is over 1,500,000 tons. It can thus be seen that the saving effected by the use of these waste heat boilers is a decided factor in the conservation of the coal of the nation. Aside from the aspect of conservation, there is a large saving in money to the users of waste heat boilers with coal at its present price—or, for that matter, at any price. The return on the investment in this class of apparatus is such that the owners of any plant where spent gases of sufficient volume and temperature are available cannot afford to disregard the possibility of a waste heat installation.

*Paper read before the Engineering Society of Western Pennsylvania.

While the term "waste heat" will in all probability continue to be used, it is obvious from the savings through its utilisation, that it is a decided misnomer in many cases.

War conditions made it imperative to minimize the cost of fuel, and great credit is due to those who labored to promote a saving and to the users of fuel who co-operated to secure the saving that was effected. On account of the increase in the cost of fuel, the attention of the engineer is now turned more earnestly than ever to the problem. We should go further than we have in the past. With apparently unlimited resources, the dollars-and-cents side—obtained by balancing the interest on capital investment, etc., against the fuel saving—has been the controlling factor in deciding whether a more economical plant should be installed to take the place of one that is recognised as being wasteful. Eventually we must consider the conservation of fuel for future generations, and it may not be long before there will be laws with this in view.

The first installations of our modern design of waste heat boilers were made in connection with open-hearth steel furnaces. Certain minor difficulties of operation arose with those first installed, but these were no greater than were to be expected with a type of apparatus essentially new in that particular field, as well as different from the same class of apparatus in use in other fields of steam generation. That the initial difficulties of operation were overcome, is borne out by the fact that there are to-day in the United States over 210 open-hearth steel furnaces equipped with such boilers, the total capacity of these furnaces being conservatively stated as 12,000,000 tons per year.

The steam engineer of to-day, while he is familiar with the use of waste heat boilers in one or possibly two classes of work, may not realise the widely varied classes of industrial plants in which waste heat boilers have been installed and are in successful operation. The tabulation following gives the different classes of industrial plants using our modern waste heat boilers:—

Open-hearth steel furnaces.
Heating furnaces.
Cement kilns.
Dolomite kilns.
Copper refining furnaces.
Nickel refining furnaces.
Zinc refining furnaces.
Gas benches.
Glass tanks.
Oil stills.
Bee-hive coke ovens.

The necessity for an increase in transfer rates in waste heat boilers, over that which exists in direct fired boilers to give results that are at all comparable, is perhaps not generally appreciated. In burning fuel under a boiler, a temperature is developed greatly in excess of the average waste gas temperature. For comparison of direct fired with waste heat practice, let us consider (1) a direct fired unit equipped with an underfeed stoker, and (2) a waste heat boiler set, in connection with oil stills. In the former case, with proper stoker operation, the furnace temperature will approach 2,700 deg. F., while in the latter case the temperature of the gases entering the boiler will be approximately 1,000 deg. F.

In direct fired practice a considerable proportion of the total heat absorbed by a boiler is absorbed through direct radiation to the tubes which are exposed to the radiant heat of the furnace. How great a proportion of the total absorption is accomplished in this manner is not ordinarily realised.

With a reasonably constant furnace temperature the amount of heat absorbed through direct radiation is, within reasonable limits, a constant, irrespective of the capacity developed by an individual boiler. It naturally follows that, as the capacity of a direct fired boiler is increased, the percentage of total absorption through radiation is decreased, as this represents the ratio of the total number of heat units absorbed from the gases (which remains constant) divided by the total heat absorbed by the boiler (which increases with capacity). In comparing direct fired with waste heat installations it is necessary, because of the comparatively low ratings developed in the latter class of work, to consider the direct fired unit operating at a low capacity.

Experiment has shown that for a furnace temperature of 2,700 deg. F. the absorption through direct radiation is, for a 4-in. tube spaced on 7-in. centres, slightly over the equivalent of 80 pounds of water evaporated per hour from and at 212 deg. F. per lineal foot of tube to direct radiant heat in the furnace—an absorption of some 77,630 B.t.u. per hour. In a 500-H.P. Babcock & Wilcox boiler, with the baffle arrangement ordinarily offered for underfeed stokers and with the boiler operating at its normal rated capacity, this evaporation, due to absorption through direct radiation, would represent approximately 66 per cent. of the total heat absorption.

The effect of absorption due to radia-

tion varies approximately as the fourth power of the absolute temperature of the radiating medium. On the basis of an absorption through radiation equivalent to an evaporation of 80 pounds per hour from and at 212 deg. per lineal foot of tube in the furnace for a temperature of 2,700 deg. F., the corresponding absorption for a furnace temperature of 1,000 deg. in the case of the waste heat boiler would be approximately 3.65 lb. from and at 212 deg. per hour per lineal foot of tube exposed. If for the sake of comparison, we assume that both the fired boiler. In a 500-H.P. direct fired unit develop their normal rated capacity, the absorption through direct radiation would be only 3 per cent. of the total absorption for the waste heat boiler as compared to 66 per cent. for the direct fired boiler. In a 500-H.P. direct fired boiler, operating at its normal rated capacity, the absorption through convection will then be equivalent to 170 H.P. If the 500-H.P. waste heat boiler is to develop its normal rated capacity, the absorption through convection must be equivalent to 485-H.P.

The temperature of the gases leaving the radiant heat zone in the direct fired boiler will be somewhat higher than the temperature of the gases entering the waste heat boiler, the relative temperature with the direct fired unit and waste heat boiler both developing the rated capacity—approximately 1,200 deg. and 1,000 deg. F., respectively. If the two units be operated at the same pressure, and the gases be cooled to the same ultimate temperature, we will have relative average temperature differences of approximately 460 deg. and 360 deg. F. The total absorption through convection is represented, approximately, by the product of the transfer rate, the heating surface, and the range of temperature difference. To develop the above capacities through convection, it would be necessary to obtain transfer rates as follows:—

Direct fired. . $R \times 5000 \times 460 = 170 \times 33{,}477$. $R = 2.47$
Waste heat. . $R \times 5000 \times 360 = 485 \times 33{,}477$. $R = 7.02$

In other words, if each of the two units is to develop its rated capacity, it would be necessary in the case of the waste heat boiler to arrange the heating surface in such a manner as to give a transfer rate more than three times as great as that in the direct fired unit. This comparison is an extreme case which has been used to indicate the necessity of high gas velocities where the gases are of low temperature; conclusions should not be drawn from it respecting the effect of the absorption of radiant heat on the efficiency of a direct fired unit as other elements enter the problem.

The heat absorption, or heat transfer rate, is dependent upon the gas velocity and not upon the number of passes, except in so far as the number of passes affect the velocity. For equal gas weights, the velocity is the principal factor affecting the transfer rate; for, at any velocity so far used in modern waste heat work, the effect of the mean temperature difference of the gas and absorbing medium is slight as compared with the velocity. Naturally, for a given transfer rate, the greater the temperature difference the greater the total heat absorption, but the temperature difference for the gas velocities employed has so slight an effect on the rate itself that any difference in the rate may be neglected.

First, assume the heating surface of a water-tube boiler with horizontally inclined tubes arranged to give the gases four passes over the tubes. If the boiler were, say, 18 tubes high, a gas particle would strike the tubes 4×18, or 72 times.

Again, take this same amount of surface arranged to give three passes of the gases in a boiler of a given width. In order to obtain the same gas velocity, and the heat transfer corresponding to such velocity in the three-pass unit, it would be necessary to reduce the length of the tubes 25 per cent. below that employed in the four-pass unit, and the equivalent amount of surface would be added in height. The three-pass unit would be 24 tubes high to give the same heating surface. In such a boiler, a gas particle would again strike the tubes 3×24 or 72 times.

Carrying the comparison to an extreme case, if the same amount of heating surface were arranged to give a single pass of the gases, still maintaining the same gas velocity and transfer rate resulting from such velocity, it would be necessary to shorten the tubes 75 per cent. This would result in a unit 72 tubes high, and a particle of gas would naturally strike the tubes 72 times as in the other case. Such an arrangement of heating surface would, of course, be impracticable, but is described to indicate the principle involved.

The heat transfer rate would be the same for the three cases considered—that is, for four passes, three passes, or a single pass; whereas the frictional resistance to the flow of the gases, or the draft drop, would increase with any increase in the number of passes, on account of the added resistance due to changing the direction of flow of the gases in the different passes.

Because of the flexibility of design, through varying the arrangement and the amount of heating surface by changing the width and height of the boiler and the length of the tubes, it is theoretically possible to give the gases any desired number of passes over the heating surface and still maintain the gas velocity which will give the greatest commercial return. Under such conditions the proper number of passes to employ in waste heat work becomes a question depending upon commercial rather than engineering factors, and these should be given consideration in each specific installation.

There is the question of cost, though because of the relatively large return on the investment with this class of apparatus this is usually not of primary importance. A single-pass boiler without baffles is the simplest unit that can be offered. With a single-pass boiler, however, in order to maintain a velocity resulting in adequate transfer rates, it is ordinarily necessary to make use of short tubes; and this leads to a construction of relatively high cost.

A second consideration in the proper number of passes to be offered is that of the point of removal of gases from the boiler setting. For any waste heat boiler where the gases enter beneath the tubes at a point corresponding to the furnace in ordinary direct fired practice, where the number of passes is made odd—that, is one, three, or five—the gases must be removed from the the setting at or near the top of the boiler. Where the number of passes is even the gases must be taken from the bottom and at the rear of the boiler.

The best arrangement to use, in most cases, is three passes. Where an overhead connection is desired, fan supports and platforms are provided. Where it is desired to place the fan and its drive on the floor, an easy connection can be made through the rear water circulators to the fan.

Economizers are frequently installed in connection with waste heat boilers. What we believe is a desirable—and certainly the most compact—arrangement of boiler and economiser, is a recently developed combination in which a three-pass boiler is used. The gases pass from the boiler, through the vertical, rear circulating tubes, directly into an economiser which is made up of horizontally inclined tubes extending transversely to the boiler setting. The gases pass downward over the economiser tubes while the water has an upward flow, a counter-flow being obtained between the water and the gases, and the water in the economiser flowing continuously upward so as to avoid any pockets should steam be formed in the economiser. The fan location is at or near the floor line. The apparatus as a whole is much more compact than one in which the boiler, economiser, fan, and fan drive are extended horizontally. Furthermore, the path of the gases over the economiser surface is downward, and experience has shown that with heavily dust-laden gases it is much easier to keep the heating surface clean where the gases flow downward than where they flow upward. This advantage, which is an important one, is not possessed by an economiser where the flow of the gases is in a horizontal direction.

Draft is the most important factor in the determination of the proper number of passes to be offered in waste heat. The draft loss through a water-tube boiler is a function of two factors—the loss due to frictional resistance to the gases in their passage over the tubes, and the loss due to the making of the turns over the baffles. In any upward pass of the gases there is a stack effect, due to the pass itself, which tends to

offset the loss due to friction; and it is no uncommon occurrence in high-temperature, direct fired practice to find a greater draft suction at the bottom than at the top of an upward pass in a boiler. In a downward pass of the gases, on the other hand, there is a negative head to be overcome in addition to friction.

In order to recover the major portion of the power used for the fan drive through utilisation of the heat in the exhaust, it is almost universal practice in waste heat work to use a steam-turbine drive for the induced draft fan. Experience has shown that with the gas velocities best adapted for this class of work, the exhaust from the fan turbine, when producing draft sufficient to overcome the total resistance through a properly designed three-pass boiler unit and giving the required draft at the outlet of the primary furnace, is just about the amount required to heat the feed-water entering the waste heat boiler to 212 deg. F. While the amount of heat recovered in this manner will, of course, vary with the gas temperature, the fan and turbine efficiency, and the class of primary furnace, the statement above may be accepted as generally correct.

Single pass, waste heat boilers without any induced draft apparatus are the simplest that can be employed and in fact it is this design that was probably among the first of the water-tube boilers used in waste-heat work. The early installations, however, were made of a low draft resistance in order not to interfere with the operation of the primary furnace.

There is a considerable field for the single pass, natural-draft, waste heat boiler even under modern conditions. In plants where such boilers are applicable, the gas temperatures are high, approaching those of direct fired practice, and greatly in excess of the temperatures for which our modern design of waste boilers was developed. This statement is not to be taken as indicating that high gas temperature alone, without taking into consideration the other factors involved, makes the installation of a single-pass unit advisable, rather than a multiple-pass unit, but to indicate the limitation of the field of usefulness of the single-pass unit.

The single-pass unit can be successfully used only in connection with a furnace requiring a low draft. In some instances, such as in a puddling furnace, the heating surface can be so arranged that the boiler itself serves to some extent as a stack; and in serving as such the available draft from a given stack, although less than if no boiler were installed, will, when added to the stack effect of the boiler, provide enough draft for operating the furnace. If, on the other hand, we consider a primary furnace from which the gases emerge at low temperatures and which requires a greater amount of draft for proper operation—such as an open-hearth steel furnace—the cooling effect due to the installation of boiler heating surface, even in a single-pass unit of low gas velocity, would reduce the available draft to a point where the furnace operation would not be possible. In open-hearth steel practice a draft of 1.5 to 2.7 in. is required at the checkers. Where no waste heat boiler is installed, with an available gas temperature of, say, 1,100 deg. to 1,200 deg. F., a stack 160ft. to 175ft. high will produce the necessary draft. If, however, there is installed a waste heat boiler which would cool the gases to, say, 600 deg. F., the stack which would give 1.6in. draft with a gas temperature of 1,200 deg. F. would give probably less than 1in. with a temperature of 600 deg. F., which would be too low for operating the furnace, even should a single-pass boiler be employed. If we allow a total draft loss, including the loss due to a single-pass unit, of 0.75in. between checkers and stack, the height in order to secure proper furnace operation would have to be about 400ft. Under such conditions it is evident that with open-hearth and similar furnaces, waste heat boilers, either single or multiple-pass, cannot be installed except in connection with induced draft.

A single-pass boiler may be used to advantage where a low weight of gas is available, as where the gas weight is small and the total cost corresponding return low, the expense of an induced draft apparatus in addition to that of the boiler may not be warranted. This applies particularly to plants where, though the gas weights are low, the temperatures are high.

A single-pass rather than a multiple-pass boiler is sometimes the best to install in the case of an isolated plant where there is no outlet for the power developed except for use at the plant. In such a case, if the single-pass, natural-draft boiler will cool the gases to a point where the steam produced will meet the total requirements for the plant, there is obviously no necessity nor object in going to the expense of a more complicated multiple-pass unit with its induced draft apparatus. Naturally, in this case, the draft requirements of the primary furnace must be such that a single-pass, natural-draft unit may be satisfactorily installed.

There is a wide difference in the economiser problem in waste heat and in direct fired practice, on account of the widely different ratios of gas to water weights in the two classes of work. If we consider a waste heat unit utilising low temperature gas, and a direct fired unit, both having the same heating surface and developing the same capacity the ratio of the gas to the water weight in the case of the former is some four times as great as the same ratio in the latter case.

While special forms of economisers can be advantageously applied, which will operate properly when steam is formed in the economiser, in the ordinary form of economiser the temperature of the feed-water leaving the economiser must be kept below that due to the pressure at which the boiler is operated, under the extreme conditions that may occur in order to avoid steaming. If steam is formed in the economiser there will be a tendency to pass the water into the boiler in slugs, which would result in a prohibitive variation in water level. Under such conditions, the water level in the boiler would rise when the steam is formed. The operator would naturally shut off the feed in an endeavour to prevent the water level in the boiler becoming too high, which would, for a time, increase the amount of steaming in the economiser. Eventually, when the water level in the boiler would fall, the economiser would be partly filled with steam, and during the time that the economiser was being filled no water would be passing to the boiler, which might cause trouble through low water in the boiler. Again, when steam is being made in the economiser, objectionable strains may be set up through heating the portions of the economiser which contain steam to a temperature in excess of that of the portions which contain water, and when water is again fed to the economiser and the steaming ceases, trouble may result from sudden cooling and from water-hammer. Obviously, under these conditions, it is necessary that the maximum temperature of feed leaving the economiser of the type considered shall be kept below the steaming temperature.

If a waste heat and a direct fired boiler having the same heating surface and developing the same capacity are equipped with the same amount and arrangement of economiser surface, the economiser fitted to the waste heat boiler will increase the temperature of feed more than the economiser fitted to the direct fired boiler. This is because of the higher ratio of gas to water weight in the case of the waste heat boiler as compared with the direct fired boiler.

Another condition that must be taken into consideration, and one which emphasizes the difference in the economiser problem for the two kinds of work, is that in direct fired practice any increase in the weight of water passing through the economiser—that is, an increase in the boiler capacity being developed—is ordinarily accompanied by a corresponding increase both in temperature and weight of gas entering the economiser; whereas, in waste heat practice, due to the possibility of irregularity in the operation of the primary furnace, there is no fixed relation between gas weight, water weight and gas temperature.

In view of the above, in order that the temperature of the feed-water leaving the economiser shall be kept below the steaming point, the amount of economiser surface that can be installed in waste heat work is greatly below that

which can be installed in direct fired practice. Furthermore, because of the possible irregularities of the operation of the primary furnace, the safe margin between the steam temperature and the temperature of the feed-water leaving the economiser must be made greater in the case of waste heat than in direct fired practice, where there is a more or less fixed relation between the functions determining economiser performance and where allowance may be more readily made for extreme conditions.

In general, in waste heat work, the economiser should be proportioned to and not in excess of 12 per cent. or 13 per cent. of the total heat absorbed by the boiler and economiser. Ordinarily, with low and moderate waste gas temperatures, this will result in an economiser which under normal conditions of operation will heat the feed to a point not closer than 60 deg. F. to the steaming temperature. While, of course, the amount of economiser surface necessary to give this result will vary with the gas weight and temperature conditions, in the average waste heat installation with entering gas temperature of from 1,000 deg. to 1,500 deg. F. it will usually be from 30 per cent. to 35 per cent. of the boiler surface.

Though not strictly dealing with the recovery of waste heat, a development that may be considered in connection with water heating boilers is the use of our modern waste heat boilers for direct fired practice. In the burning of a fuel under a boiler, if high furnace temperatures are developed and sufficient heating surface is exposed to radiant heat in the furnace, the absorption due to direct radiation is ordinarily a large proportion of the whole. To develop the same capacity from a given boiler, with fuels such as blast-furnace gas, where it is neither practicable nor possible to obtain high furnace temperatures, the amount of heat absorbed through convection compared to that absorbed through radiation must be greater than in the case of the high furnace temperature unit. In this case, it is advantageous to apply the principles of our modern waste heat boiler design.

While furnace temperatures of 2,200 deg. or 2,300 deg. F. are theoretically obtainable with blast-furnace gas, it is probable that, even with the best design of burners, the temperatures do not average over 2,000 F. with this furnace temperature, the absorption through radiation will be less than 40 per cent. of that absorbed through radiation with a furnace temperature of 2,700 deg. If, therefore, the total return from blast-furnace gas is to be made comparable with that to be expected in high-temperature work, it becomes necessary to increase the percentage of total absorption through convection.

Until the past few years blast-furnace gas was regarded as more or less of a waste product. No particular effort was made to develop an efficient method of burning the gas and, as in the case of early waste heat work, any steam generated through its use was simply accepted as "something for nothing." As indicative of the efficiencies secured with blast-furnace gas, quotations from a paper presented before the American Iron and Steel Institute, by Mr. Ambrose N. Diehl, are of interest:

"The average efficiency of a blast-furnace plant, using common burners and operating without the aid of technical supervision, is not over 50 per cent., and frequently much lower. . . .

"Of a total of 60 blast-furnaces in the Corporation under observance, the tests and information from the operators indicate a practice of not exceeding 55 per cent. The increase of 10 per cent. probably possible with improved conditions will show a yearly saving of one and one-half million dollars."

In line with other movements toward general conservation, steel-mill operators began to realise that any increase in the efficiency with which they could burn blast-furnace gas would result in a decrease in the consumption of a higher cost fuel in other portions of the plant.

Assuming a furnace of proper form and volume, the logical starting point in the development of any improved method of burning the fuel in question, was in the design of the gas burners. The designers and manufacturers of blast-furnace gas burners developed their product to a point where they were able to burn this fuel more efficiently than in the older practice. For combustion completed within the furnace the conditions were similar in all essential details to those under which our waste heat boilers had given eminently successful results. The gas temperatures entering the heating surface were no higher than in bee-hive coke-oven and in certain classes of heating furnace waste heat work. The gas weight, in common with waste heat practice, was higher than for coal firing; for, even with a minimum of excess air, the weight of products for combustion for blast-furnace gas is some 75 pounds or 80 pounds per boiler horse-power developed, as against 45 pounds or 50 pounds in the case of underfeed stokers. The furnace volume and the length of gas travel are the important factors. The furnace volume measured in cubic feet per rated boiler horse-power, is some three times as great as the volume formerly believed to be ample in this kind of work. The furnace arrangement, is in general, designed to secure a maximum furnace temperature, rather than to expose any large proportion of the tube surface to the action of the radiant heat. These modern units operating at about their rated capacity are showing efficiencies of some 76 per cent. When operating at 200 per cent. of normal rating the efficiencies are approximately 73 per cent.

PERSONAL

Ethan Viall, for ten years a member of the staff of the American Machinist, has resigned as editor-in-chief to become a member of the firm of T. W. Minton & Co., Barbourville, Kentucky, U.S.A., the largest producers of hickory dimension stock in the country. Previous to joining the staff of the American Machinist Mr. Viall was associate editor of Machinery, and before that he was for fourteen years foreman and superintendent in several of the largest specialty manufacturing plants in the Middle West. He was at that time also a frequent contributor to Canadian Machinery and other technical journals. He is a member of the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, the Society of Automotive Engineers, the American Welding Society, the American Society for Testing Materials, and the Franklin Institute. He is author of Broaches and Broaching, Gas Torch and Thermit Welding, Electric Welding, United States Artillery Ammunition, United States Rifles and Machine Guns, and the Manufacture of Artillery Ammunition. The last named book was compiled by the staff of the American Machinist largely from material gathered in Canada during the early days of the World War, and did much to assist shop men in fitting up for munition work. Mr. Viall is especially well known to the machine tool men around Cincinnati, Cleveland, Detroit and throughout the Middle West, where he travelled for six years in the interest of his paper.

Modern fireproof buildings will be built to replace those destroyed by fire at the Muskoka Free Hospital at Gravenhurst. The cost of the buildings will be $175,000 and with the necessary equipment the total expenditure will be $250,000.

Let Contracts.—Premier Foster of New Brunswick announced that contracts for machinery for the hydro-electric installation at the Musquash River had been awarded on the recommendation of the water powers commission. The contractors and the contract prices are as follows: S. Morgan Smith, $93,056, hydraulic machinery; Canadian General Company, $162,000, electrical machinery.

Boiler Exploded.—One man was killed and eight others injured when a small boiler used for heating water in connection with operations on the new cooperage factory at Fort Coulonge, Quebec, exploded, wrecking the boiler room of the building and sending flying debris and scalding water into a crowd of workmen. The factory belongs to the Sutherland-Innes Company, Limited, of Sunbridge, Ontario. Two of the injured were taken to Ottawa.

A Course of Instruction for the Graded Certificate

We Will in This Course Go Through the Mathematical and Theoretical Work to Cover Every Grade of Certificate Issued by the Ontario Board

By T. H. FENNER

WE have dealt in the previous articles of this course with the vessels that are used for the generating of steam from water. It has been shown on what principles their construction is based, and the means of obtaining the necessary strength to resist the internal pressure placed upon them. Before being in a position to discuss the action of steam in the prime movers, the student must first form a proper idea of what steam is, and what makes it capable of doing the work which it performs.

Heat

First of all, just as we explained that coal was merely a vehicle for the storage of heat, we must imagine steam to be also a mode of storing and conveying heat. The heat which was stored up in the coal has been released by combustion, conducted through the boiler plates to the water, where it has been absorbed until sufficient heat has been present to change the water into steam, and is now present in the steam. The steam will carry it out through the valves and pipes into the machines, either reciprocating or rotary. Here some of the heat will be given up by doing work, but only a small portion of it. The greater part will be carried away to the atmosphere and lost, or carried off in the circulating water and lost, or it may be usefully employed in heating a building or heating water, or some other purpose.

We have been speaking of heat as though it was something that could be picked up and carried about, and this was the conception that the early investigators had of it. They imagined heat was a substance that could be handled like water, ice, coal, or any other material. As time went on, and this elusive material could not be found in any definite form, new ideas were formed. The fact that heat could be generated by the rubbing together of two surfaces turned the investigators' thoughts to the relation between heat and motion, and from the field opened up by that channel our present theory of heat has grown.

Heat, as it is now understood, is energy or motion. That is, the gain or loss of heat by a body can only be performed through a gain or loss in energy. The body that receives the heat is made capable of performing work, and the disappearance of heat is always accompanied by the giving out of energy, or the performance of work. This work may be either external or internal, which means it may be performed entirely in the body itself, in changing its shape, or it may be performed on an external object, such as moving a piston. For instance, the work performed in changing a liquid to a gas is internal work, while the work done by the gas in a mechanical machine is external work.

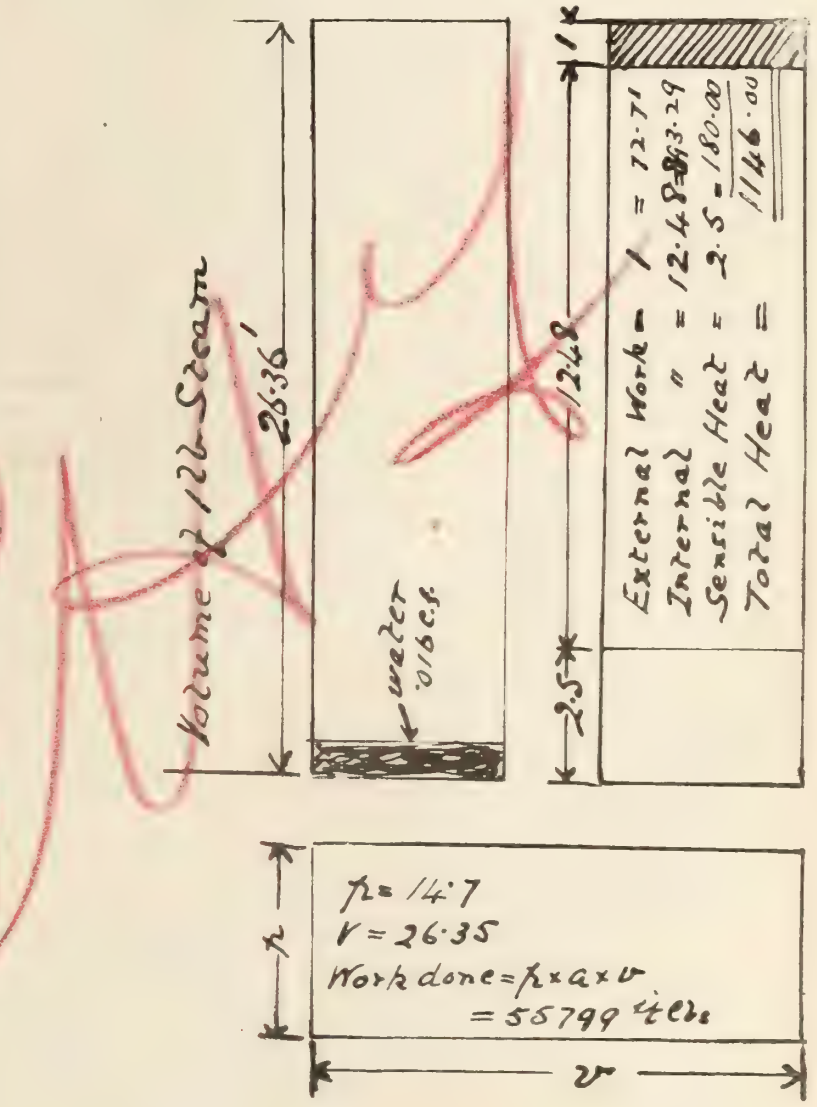
Relation of Heat and Work

We gave at the beginning of this course the laws governing the relation of heat and work. However, for the benefit of those readers who have taken it up since then we will repeat them.

The unit of heat, known as the British thermal unit, is the quantity of heat required to raise 1 pound of water 1 deg. F. when at its maximum density, that is, 39 deg. F.

The unit of work is the foot pound, which means the amount of work that is performed by raising one pound weight one foot high.

A definite relation exists between these two units, and one that is most important to realize. We have said that heat and work are mutually convertible, and therefore one unit of heat must be in a definite proportion to the unit of work. This relation has been definitely established by eminent investigators, who have found that 1 unit of heat, or 1 B.t.u., is equal to 778 units of work, or foot pounds. That means that the quantity of heat required to raise the temperature of one pound of water one degree contains sufficient energy to raise one pound weight 778 feet high.



Sensible and Latent Heat

Having established the relation be-

tween heat and work, we can now consider the action of raising water to boiling point, and then changing it from a liquid to a gas. In considering this phenomenon we will come across the problem of sensible heat and latent heat. Sensible heat may be defined as heat that applied to a body increases its temperature and is capable of being detected by the senses and measured on a scale. Latent heat is heat that is employed in performing internal work in the body itself, and is not apparent or capable of being measured by ordinary instruments. These definitions are all right in themselves, but we must go further than this to get a clear idea of the properties of these two kinds of heat. The clearest way in which to illustrate this is by means of a diagram.

If we have 1 pound of water at a temperature of 32 deg. in a cylinder whose area is exactly 1 square foot, and on top of the water have a weightless, frictionless piston, which is open to the atmospheric pressure, the weight on the piston will be equal to $a \times p$, where a=area of piston, and p=atmospheric pressure. Suppose now we apply heat to the bottom of the cylinder, and raise the temperature of the water to 212 deg., which is the boiling point at atmospheric pressure. We will have added 212—32=180 degrees to the temperature of the water, and the volume will have been increased but very slightly. If now we continue to apply heat, there will be no further raise of temperature, and no change of volume until the water starts to evaporate. The piston will then start to rise until we have evaporated all the water and in place of the water have 1 pound of saturated steam at atmospheric pressure and the same temperature. Now let us see what has occurred. The weight of one cubic foot of water is 62.5 pounds, so that the volume of one pound of water is $1 \div 62.5$ or .016 cubic foot. The volume of one pound of steam at atmospheric pressure is 26.36 cubic feet, so that we have raised the piston against atmospheric pressure a distance of 26.36 —.016, which is practically 26.35 feet. Now we have seen earlier that work is the product of force by displacement, and that it is measured in units known as foot pounds. Therefore we have, in performing the work of raising the piston, expended

$$26.35 \times 14.7 \times 144 = 55{,}799 \text{ foot pounds.}$$

Now we know that 778 foot pounds are contained in one unit of heat, therefore the heat units used are

$$55{,}799 \div 778 = 71.72.$$

Now we have put into the water very many more heat units than this. The total heat of steam above 32 degrees at atmospheric pressure is 1,146 B.t.u., which is made up of 180 B.t.u. of sensible heat, and the balance 966 B.t.u. of latent heat. So that of the 966 heat units which have been absorbed into the steam only 71.72 have done any useful work. If the water had been allowed to evaporate freely into the atmosphere after reaching the boiling point, the whole of the latent heat and sensible heat would have been carried away.

To come back to our diagram. The sensible heat is 180. The latent heat absorbed in internal work is 966—71.72 =896.28, and the external work, which has been given out on raising the piston is 71.72, all in B.t.u. This is in the proportion of 71.72 : 180 : 894.28 or 1 : 2.5 : 12.47. We can show these proportions by the rectangular areas of our diagram. The proportion that goes to perform useful work is represented by the small shaded area at the top, and this is also a measure of the efficiency of the steam. This efficiency is of course the ratio of the useful heat to the total heat put into the steam. The whole diagram is exactly what would take place in a non-expansive steam engine, that is an engine carrying the steam the whole stroke. Now we have 71.72 B.t.u. useful work to 1,146 B.t.u. put in and the efficiency will be

$$71.72 \div 1{,}146 \times 100 = 6.25 \text{ per cent.}$$

Supposing now we surrounded our cylinder with cold water, and condensed the steam until we had again our one pound of water at 32 deg. temperature, and a volume of .016 cubic foot. The heat that was put into the water to raise the temperature and to perform the internal work must be returned. Where will it go? It will be absorbed by the condensing water, raising the temperature of the latter. The condensing being performed at atmospheric pressure, just as the evaporating was, the external work put into the piston to raise it against atmospheric pressure will be given out again in causing it to descend the same distance, against the same pressure. Therefore, the total heat rejected to the condenser will be equal to the total heat supplied to the water originally, or if Q=total heat of evaporation, and R=heat rejected, Q=R. This is a strictly elementary case, and we have not taken into account any loss by radiation through the walls or condensation on the walls of the cylinder which would occur in actual practice.

Let us now consider a case where we are evaporating steam at a pressure higher than atmospheric. Suppose we have our water again at 32 deg., and evaporate it to steam against a pressure of 100 pounds absolute, or roughly 7 atmospheres. The first thing we shall find is an increase in the sensible heat, or, in other words, a higher boiling point. The boiling point of water at 100 pounds pressure is 327.7 deg. We have therefore to add 327.7—32=295.7 B.t.u. to the water before we reach boiling point. To turn the water into steam at 100 pounds absolute pressure we must now add 884 B.t.u., which is the latent heat or heat absorbed in the steam. Now as the pressure increases the volume decreases and we find the volume of one pound steam at 100 pounds absolute pressure is 4.35 C. F. Let us now compare the internal and external work. The total weight on the piston will be 144×100 and the work done will be $144 \times 100 \times (4.35 - .016)$. The volume of the water will be so small in comparison that we may safely neglect it, and assume the work done to be $144 \times 100 \times 4.35 = 62{,}640$. The external work expressed in heat units will be

$$62{,}640 \div 778 = 80.5 \text{ B.t.u.}$$

The total heat is 1,181.9, or nearly 1,182, and the efficiency will therefore be

$$80.5 \div 1{,}182 \times 100 = 6.8 \text{ per cent.}$$

Here we see that the efficiency of steam under these conditions is but very little greater than that of atmospheric pressure. The gain in using high pressure steam without expansion is very slight indeed, but when we consider it used expansively we will see a difference.

Let us now consider the effect of heating the water, or rather of making steam from water of a higher temperature than 32 deg. Suppose we have our water at 100 deg. to begin with. Then to bring it up to the boiling point we have to add only $295.7 - (100 - 32) = 227.7$ B.t.u. The latent heat is the same, 884, so that we now have added only $227.7 + 884 = 1{,}111.7$ B.t.u. altogther. Now the external work will be the same, 80.5, and the efficiency will be

$$80.5 \div 1{,}111.7 \times 100 = 7.2 \text{ per cent.}$$

That is, we have increased the steam efficiency from 6.8 per cent. to 7.2 per cent. We have, however, instead of putting in 1,182 B.t.u. only put in 1,112 roughly, or 70 B.t.u. less, so that the saving in heat is $70 \div 1{,}182 \times 100 = 5.9$ per cent., say 6 per cent. If this added initial heat be gained from a source which would otherwise have been lost, the saving is apparent.

We have considered the case where our piston having been raised by the steam was brought back to its original position by the condensation of the steam at the same pressure. In this case we have seen that all the heat that was put into the steam was rejected to the condensing water, thus making the work usefully employed nil. That is the piston had work put into it to raise it, but had to give out that work again in descending. We will now consider the effect of removing the pressure from under the piston entirely when the steam is condensed. In other words, imagine the steam to be opened to a condenser in which there is a perfect vacuum. It is obvious that in this case the piston in descending will have no resistance to overcome. That is, there will be no force used, though the displacement takes place. Or else consider that the pressure of the atmosphere is removed at the moment the steam is condensed, and being weightless the piston remains poised where it is. Either way amounts to the same thing, for no work is done in either case. We then will have less heat rejected to the condensing water, by the amount of the external work. The heat rejected will be the total heat Q minus the external work E, and the equation for heat rejected will be Q—E=R, or in

the first case we considered 1,146—71.7 =R. The 71.7 then becomes useful work, and the heat rejected to the condenser is 1,146—71.7=1,074.3 B.t.u.

If now, instead of condensing in a perfect vacuum, or at zero pressure, the condensation takes place at a back pressure of 2 pounds absolute. Then the work done by the falling piston will be $14.7 \div 2 \times 71.7$, or approximately 10 B.t.u. Then the heat rejected will be

$$Q-(E-10)=R$$
$$1,146-61.7=1,084.3.$$

Then the efficiency will be: Heat put in — Heat rejected ÷ Heat put in, or

$$\frac{Q-R}{Q}=\frac{1,146-1,084.3}{1,146}=\frac{61.7}{1,146}\times 100=5.3\%$$

From the foregoing we can get a formula to express the same results. If H=total heat, L=latent heat, and S=sensible heat, then H=L+S. Now S is equal to the temperature of steam, t, minus 32 or S=(t—32). The latent heat of steam at any temperature may be found from the formula 966—.7(t—212), so the expression for H becomes

$$H=(t-32)+966-.7(t-212)$$
$$=t-32+966-.7t+148.4$$
$$=1,082.4+.3t.$$

Now the heat lost by the steam is equal to the heat gained by the condensing water, and may be expressed as follows. In the first case where all the heat was lost. Taking one pound of steam, and supposing the final temperature of the condensing water to be t_3, the initial temperature to be t_2, and temperature of steam to be t_1. Let x=number of pounds condensing water required. Then $H=1(t_1-32)+966-.7(t-212)$ and the gain of heat by water $=x(t_3-t_2)$, we have

$$1(t_1-32)+966-.7(t-212)=x(t_3-t_2)$$
$$x=\frac{1,082.4+.3t}{t_3-t_2}$$

Substituting figures, suppose the initial temperature of water to be 40 deg., and final temperature 100 deg. Temperature of steam 212 deg.

$$1(212-32)+966-.7(212-212)=x(100-40)$$
$$180+966=x60$$
$$x=(1,146\div 60)=19.1 \text{ pounds.}$$

Now suppose we had only wished to mix water at 212 deg. with sufficient water to make the mixture 100 deg., we should have only required

$$1\times 212=x(100-40)$$
$$x=212\div 60=3.53 \text{ pounds.}$$

This shows the influence of latent heat.

The formula for latent heat may be expressed in shorter form, thus:

$$966-.7(t-212)$$
$$=966-.7t+148.4$$
$$=1,114.4-.7t.$$

Then total heat $=(t-32)+1,114.4-.7t$.

Suppose we wish to find the latent heat of steam at a temperature of 212. Then

$$L=1,114.4-.7\times 212$$
$$1,114.4-148.4$$
$$=966.0$$

and total heat will be $(212-32)+966$

$$=180+966$$
$$=1,146.$$

Making Pipe Bushings From Standard Pipe

By W. F. SCHAPHORST. Copyright in U.S.A., 1920.

IT IS a good thing to know that bushings can be made out of standard pipe. Many pipe fitters don't know that it can be done. Or, if they know that it can be done they don't know the correct size of drill to use for tapping. I have always known that it can be done and have occasionally made bushings out of pipe, but each time I found it necessary to first look into my handbook for the drill size to use and that is so much trouble that it is frequently easier to go to the store and buy a new bushing. Recently, though, it has been very difficult to buy bushings in stores on account of shortage of all pipe fittings, hence I feel that the following information should be of much value. I have collected all of the data together for all bushings that can be made out of ordinary sizes of extra heavy and double extra heavy piping.

To bush from ¼" to ⅛," for example, get a piece of ¼" extra heavy pipe sufficiently long for cutting the outside thread. Then cut the end off to the desired length, drill or ream with a 21/64" drill (diameter of drill 0.328") and then tap with a ⅛" pipe tap. That's all there is to it.

The table enclosed tells the complete story for all ordinary sizes. Note that in one case, ⅜" to ¼", the internal diameter of ⅜" extra heavy pipe is such that no drilling is necessary.

Also note that in bushing from ½" to ⅜" either extra heavy or double extra heavy piping can be used.

To Bush From	Use This Size of Pipe	Use This Size Drill or Reamer
¼" to ⅛"	¼" Extra Heavy	21/64" Drill 0.328"
⅜" to ¼"	⅜" " "	None
½" to ¼"	½" Double Extra Heavy	21/64" Drill 0.328"
½" to ¼"	½" " " "	27/64" Drill 0.422"
½" to ⅜"	½" " " "	9/16" Drill 0.562"
½" to ⅜"	½" Extra Heavy	9/16" Drill 0.562"
¾" to ⅜"	¾" Double Extra Heavy	9/16" Drill 0.562"
¾" to ½"	¾" " " "	11/16" Drill 0.688"
1" to ¾"	1" " " "	29/32" Drill 0.907"
1¼" to 1"	1¼" " " "	1⅛" Drill 0.125"
1½" to 1"	1½" " " "	1⅛" Drill 0.125"
1½" to 1¼"	1½" " " "	1 15/32" Drill 1.468"
2" to 1½"	2" " " "	1 23/32" Drill 1.72"
2½" to 2"	2½" " " "	2 3/16" Drill 2.187"
3" to 2½"	3" " " "	2 9/16" Drill 2.562"
3½" to 3"	3½" " " "	3 3/16" Drill 3.187"
4" to 3½"	4" " " "	3 11/16" Drill 3.688"
4½" to 4"	4½" " " "	4 3/16" Drill 4.187"

HOW TO STRAIGHTEN WIRE

By L. P. Roberts

(Copyright. All rights reserved)

A convenient wire straightener is shown herewith. Two blocks of ⅞-inch board are hinged together at one end and have a number of different-diameter holes bored through them to accommodate the various sizes of wire. To straighten the wire it is merely pulled through the holes in the block.

A Year of Graded Certificates

THE act requiring the stationary engineer in Ontario to hold a certificate of a certain grade in order to operate a plant of a definite size has now been in force for one year, or will have been at the end of this month. During that year quite a number of engineers have availed themselves of the opportunity of obtaining a certificate of the highest grade, while a larger number have obtained the second-class certificate. The actual numbers are, of course, not yet available, but will no doubt be made public in the annual report of the department when that is issued. The Board suffered the loss during the year of the late W. C. McGhie, the first chairman of the Board, and a widely known and popular man among the engineering community. The position was left vacant for a considerable time, the work of the Board being carried on in the meantime by Mr. Mosely, whom it was expected would be the appointee for the vacant chairmanship. This did not turn out to be the case, as Mr. Brown was recently appointed by the Minister to carry on the work. This gentleman is well fitted by his experience and training for the work and the appointment met with satisfaction generally.

The administration of the act, has, we believe, been conducted with a spirit of absolute fairness to all, and we have heard no definite statement to the contrary. On the other hand we have received a number of vague statements regarding men who have received certificates of a grade to which they were not entitled. To all these correspondents we have returned the same answer, that they should procure definite proofs of what they state, and then submit their case. None of them have done so, but on the other hand we know of at least one case where a man secured a certificate by making a false statement of his experience, a fact that was brought to the knowledge of the Board. The action taken by them was swift and definite, and such as to discourage any further attempts along this line.

Power House holds no brief either for or against the Board, but from what we have seen we are convinced that they are absolutely fair. What we wish to convey is that if anyone knows of a case where a man has been granted a certificate that he is not entitled to, that case with all the facts should be brought to the attention of the Board. If there has been any injustice we believe that the Board will rectify it. If any case arises where there is injustice clearly proven and investigation or rectification refused, then we shall be only too glad to take it up and give all possible assistance to the cause of the right. We do not believe there are any such cases, but that is our position in the matter.

During the year a change was made in the rating of plants which could be operated under the different grades of certificates, by which a third-class certificate is sufficient for a plant up to 200 h.p. and a second-class up to 600 h.p. This gives the holders of these grades a wider latitude when seeking or changing positions and is a great benefit to them.

We believe from the results of this first year that the Ontario certificate will gradually become known in the other provinces as something worth having. The holder of a certificate of the 1st class for Ontario will have no difficulty in obtaining the first-class in any other province of Canada and the same will apply to the lower grades. The Ontario Stationary Engineers' Certificate will be in the future a thing to prize, instead of as in the past, a thing to laugh at.

New Year Resolutions for the Chief

THE time is approaching when we shall all, from long habit, make good resolutions, which will be kept for a greater or less period, according to how arduous they are to carry out. The chief engineer of a power plant should make up his mind that he will aim for a higher efficiency in his plant during the coming year than he has ever achieved in former years. This will keep him sufficiently busy during the year to prevent him having time to break any other resolutions he may have made on the side. On the other hand, keeping a plant at the top-notch of efficiency that the equipment he has will allow will show such good results that it will be an easy matter for him to persuade the management that much better performance could be shown if the additional equipment he has been asking for so long should be installed. Then it will be easier for him to maintain the results already obtained and get better ones, so that gradually his work will be decreased and his value proportionately increased. There are but very few plants where it is not possible to show results if the losses are gone after in a systematic manner and one of the first things that should be done is to get the physical condition of the plant up to the highest mark. It is of little use having a furnace which is giving the highest efficiency of combustion if the steam that is generated is allowed to wander away through leaky joints and glands without usefully giving up the heat that it has absorbed from the furnace. You may have the steam valves set to a nicety when the engine is still, but if they are allowing steam to leak through to the cylinder when they should be shut, the accuracy of opening and closing is not sufficient to make up for the effects of leakage. In Corliss engines and in engines like the McIntosh Seymour, lost motion on the various links will seriously interfere with the steam distribution in the cylinder, besides making an unpleasant noise and increasing wear and tear. In a

power plant there is nothing more true than the old adage of a stitch in time saving nine. Get after the little things before they have time to become big things and life in the engine room will become easier in consequence. When boilers, furnace, engines and pumps are in such working order that they can be safely left to the ordinary attendants, then the chief can go with a clear mind to the task of chasing the elusive B.t.u., but when he is being called every five minutes to a knock that seems to be getting worse, he has but a poor chance of looking under the surface for the faults that have to be traced. At the same time he should make it a point to get enough relaxation to keep himself in proper condition as well as the plant. Man does not live by bread alone and some recreation is a necessity.

Oil Versus Coal

REPORTS from Vancouver state that on account of the oil shortage, oil-burning equipment in boats and locomotives is being taken out and replaced by coal burners.

There is something in this move that may cause a number of very careful students to make one of those "I-told-you-so" remarks. For some time the view has been held that oil-burning equipment was being boomed out of all proportion—that it could never live up to all the advance notices that were being put up for it.

There is a shortage of oil, so marked in fact that it is not possible to secure the 70,000 barrels daily the Canadian Pacific requires.

There must be fuel for the automobiles, joy-riders and others, no matter if there is no fuel for locomotive and steamships.

Many a firm that has spent its good money in perfecting coal-burning apparatus could hardly be blamed for getting a little hot under the collar by the booming that has accompanied every move made by the oil burners.

The oil burning type has many advantages; it is easier to operate; it gives almost a maximum heat right at the start.

But when there is no fuel oil to be had, or when it is in very limited quantities, what then?

The oil burning equipment is desirable on railroads that run through wooded sections, for the foot-hill country of British Columbia, Oregon and other coast territory can bear gaunt testimony of the way in which the old belching locomotive used to strew its live coals on dry material along the right-of-way.

It is an expensive proposition changing over from oil to coal burning equipment. For a locomotive the cost might be from $10,000 to $12,000, while a fair-sized steamer of the ocean-going sort could hardly be altered for less than $50,000 or $60,000.

The coal burner will be with us for some days, and the part of wisdom is to use every possible means devised and improved for getting as much energy as possible out of every ton of coal burned.

The oil burner will be here, too. There is plenty of room for them both.

Strength of Materials

OUR knowledge of materials, particularly metals, has increased to a great extent within the past few years, but according to Professor F. C. Jenkins, president of the Engineering Section of the British Association, we are, as yet, only on the threshold of that complete knowledge which is essential before we can really tell the cause of a failure, or provide with certainty against accidents.

He states as follows: surely an engineer should be able to say whether a cylinder is safe without dropping it from the roof or rolling it down the front doorstep to see if it breaks. The time has come when the fundamental data on which the engineering theories of the strength and suitability of materials are based require thorough overhauling and revision.

When one considers the matter carefully, the professor is not far from wrong. Judging from some of the formulae we have seen, it would be a much better plan to drop the part under discussion and see if it would break, rather than try to figure out the theoretical chances of its proving too weak.

This condition should not exist, and if sufficient research work is made in this particular field, there is no reason why the formulae can not be simplified to a great extent. We should not have to depend on actual physical tests, but should be able to figure with certainty the strength of our various materials.

Cases exist where theoretical tests alone would not suffice. For example, suppose some structure is being built on which life depends. In such a case both theoretical and physical tests are made. Every boiler must undergo a water test before being fit for use, the various members of a bridge must be tested for their physical properties, and so on.

These precautions are essential with all due respect to theory, because defects can, and do, occur in process of manufacture. Theory does not allow for such defects, therefore they must be checked up by physical tests.

A great need exists, however, of our present formulae being simplified. Here is a chance for the heads of our colleges. Let them concentrate on the task, for by so doing they will be rendering a real service to the machine tool industry.

Mechanical Accuracy

"TAKE a hair from your head (the average is about 2½ thousandths of an inch in thickness) and if you could split that hair into ten strands of uniform dimensions, just one of those strands would give a fair conception of the closeness to a mean standard prescribed in more than 300 operations on our car.

"Our work calls for more than 5,000 operations in which the deviation from a mean standard is not permitted to exceed the one one-thousandth of an inch; more than 1,200 in which it is not permitted to exceed a half one one-thousandth, and more than 300 in which it is not permitted to exceed a quarter of a thousandth."

These statements appeared recently in a wide advertising campaign carried out in various national magazines, and were prepared to appeal to mechanical men in general.

Can you imagine such technical copy reaching the columns of popular magazines, even ten years ago?

It is only another proof that this is becoming more and more a mechanical age and that things are changing for the better.

Why are the limits held so close? Simply to obtain accuracy and an interchangeable product. We owe a great deal to the automotive industry in this respect, for they have been largely responsible for our seeking after interchangeability.

Working to fine limits became common practice in Canada during the days of the shell shop. We hear much of the shell-buster-funny chap no doubt. But we don't hear so much about many mechanics who had never measured anything much closer than a sixteenth.

Memory recalls one chap who used to carry a brass rule in his overalls' pocket. He could work to sixteenths all right. The question of shells was put up to him and after a study of the required standards he explained that it was out of the question—it couldn't be done in his shop.

What happened? Simply that in a few months he was working in thousandths of inches and turning out a good shell.

Fine limits indicate high class machine shop and tool room practice, as well as excellence of design. Canadian shops should never drop from these standards of mechanical superiority.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

PUMP OR INJECTOR

Question.—I am fitting up a small boiler, about thirty horse-power, and would like to know whether a pump or injector would be the best for feeding it?

Answer.—The question of fitting pump or injector depends on the conditions. If your boiler is going to run an engine, and the exhaust be used for heating purposes, a pump is more suitable as being able to handle the hot feed water. An injector, while being very inefficient in the sense of pounds water lifted to pounds steam used is, on the other hand, efficient in that it returns practically all the heat of the steam back to the boiler. For a small plant the injector is handy and low in first cost, and costs practically nothing for maintenance. A pump is very wasteful of steam, requires a fair amount of maintenance, but, on the other hand, is able to keep a more regular feed rate and can handle hot feed water. On a small boiler such as you describe, the injector would be quite suitable.

HORSE-POWER FOR DYNAMO

Question.—What horse-power will be required to drive a direct connected generator delivering 85 h.p.?

Answer.—The horse-power of the engine will have to be sufficiently high to overcome friction losses in engine and generator. The loss in the engine may be figured at 10 per cent., and if the generator is 95 per cent. efficient the engine must have 15 per cent. more power than the generator. That would be

$$\frac{85 \times 115}{100} = 98$$

horse-power, or an engine of 100 I.h.p. would fill the bill.

Capacity of Bin

Question.—We have a coal bin of the following dimensions: 19 feet 6 inches by 17 feet by 6 feet high. How much coal is in the bin, and how do you determine the quantity.

Answer.—The bin you mention will contain about 50 tons. The method is to multiply together the length, breadth and height of the bin, which gives you the cubical contents. These must be divided by 40 if the coal is of average size, as there is about 40 cubic feet to a ton of coal. If the coal is very fine it would only occupy about 35 feet, and very large, lumpy coal might run as high as 45 cubic feet. The following is the calculation for the dimensions you give: $19.42 \times 17 \times 6 = 1980.84$ and this divided by 40 gives 49.52 tons.

ALTERING CUT-OFF

Question.—In a compound or triple expansion engine what is the effect of, (1), making the cut-off in high pressure cylinder earlier; (2), altering cut-off in the other cylinders, making it either earlier or later?

The power of a compound engine depends on the weight of steam delivered to the high pressure cylinder. Cutting-off early in the high pressure cylinder decreases the power of the engine as a whole, while making the cut-off later increases the power. Leaving cut-off the same in the high pressure cylinder and altering the low, or altering intermediate and low in a triple engine, merely changes the distribution of power in the different cylinders, leaving the total power the same. For instance, making cut-off similar in the low pressure cylinder of a compound engine decreases the power of the high and increases the power of the low pressure. This is because the mean pressure of the high is decreased through having a high back pressure, due to early cut-off in the low. The low is increased, because while cut-off is earlier, initial pressure is higher.

HIGH OR LOW PRESSURE

Question.—In a building which is to be heated with live steam is there any advantage in using high pressure steam as against steam at, say, 10 lbs. per square inch?

Answer.—There is nothing gained in using high pressure steam for ordinary heating purposes. In special cases, where high temperatures have to be reached, it is compulsory to use steam having the necessary temperature. For ordinary heating the use of high pressure steam means more initial cost, higher maintenance costs, and more actual fuel costs. The temperature of steam at 10 lbs. gauge is 240 degrees, and the total heat 1,160 B.t.u., while at 100 lbs. gauge the temperature is 339 degrees, and the total heat 1,189. Thus while the temperature is very much higher, the total heat is not so much more. The higher temperature means much greater radiation losses from pipes between the boiler and the rooms to be heated, greater losses from the boiler itself, and greater wear and tear on the whole system. Allowing that the steam is kept in the coil until it is condensed, it will yield up only 29 more B.t.u. than the low pressure steam, and less of the total heat will be usefully employed.

BURNING WOOD REFUSE

Question:—I am operating a steam boiler of the horizontal return tubular type and used for heating purposes only. The heating system is a one-pipe overhead and the return water comes back by gravity and returns to the bottom of the boiler by a 5-inch pipe. The boiler is 16 feet by 60 inches diameter, having 3-inch tubes. It is only necessary to carry from 6 to 8 pounds steam pressure to heat the building, which is fairly large, with the grade of coal I am using and firing by hand, and I can obtain good results.

Now, I have been experimenting a lot lately on the saving and economy of fuel by burning a lot of our plant refuse, namely, sawdust, shavings and small blocks of wood mixed in it. Now, my experience with this is that I cannot raise my steam pressure above 3 to 4 pounds, although I have a much greater fire and longer flame than I ever have with the grade of coal I am burning. I wonder if you would be kind enough to tell me in your next issue of Power House just why I can't get a very good steam pressure with this sort of fuel, as I was of the impression that my furnace temperature would be very high and steaming up would be a rather easy matter with this fuel fired by hand. I have tried to arrange drafts to get the proper mixture of air but without results.

Answer:—Your experience in burning wood refuse is not unusual, and is easily accounted for. The value of wood as a fuel is only about one-third that of coal, or some authorities give 2¼ pounds wood to equal 1 pound coal. With the ordinary boiler setting and the usual size of fire grate it is difficult to burn the required amount of sawdust, shavings, etc., per hour to obtain the same rate of evaporation per hour as you were getting with the coal. If your boiler is not set close to the grate bars, this will be a further drawback. Wood requires a large combustion space, and with the ordinary

setting the gases come in contact with the shell of the boiler, and are extinguished before proper combustion is completed. The gases are carried away too quickly to do their work. With the ordinary fire bars and setting, it is difficult to get the correct amount of air to mix with the fuel, and if the bars are covered altogether with fuel it is worse. The bars should be of semi-circular form, and perforated, and the sawdust should be kept back from the front of the dead plate about one foot, and kept high in the middle of the grate. This of course makes your grate area smaller. The only really satisfactory way to burn shavings and sawdust is in a Dutch oven, which allows the whole length under the boiler to be a combustion chamber. If you have moisture in the shavings you are again losing heat value, in the ratio of 1.1 deg. heat value to 1 per cent. moisture.

ELECTRIC GENERATING APPARATUS

The Dodge Manufacturing Co., Mishewaka, Ind., have placed on the market an electric generating apparatus that is of rather interesting design. The photograph herewith shows clearly its general construction, and this outfit consists of complete power units for electric generating. Tests have been made on these units in strict accordance with the rules adopted by the American Institute of Electrical Engineers.

The generating units are made up either direct connected or belted in all standard voltages using Dodge heavy oil engines as motive power. The sizes manufactured at present range from 12½ h.p. to and including 75 h.p. The wide range of sizes in these outfits makes the fact evident that the power units are equally adaptable to either marine or stationary power plant service.

Oil Engine Used as Prime Mover

The heavy oil engine used is said to be sufficient guarantee of low cost operation, which of course results in a great saving in the cost of current generation. The engine is sold under a standard guarantee which specifies a consumption of fuel oil of .5 lb. per B.H.P. hour, using fuel as low as .28 Baume, containing not less than 18,500 B. t.u. per pound. It is said that every engine turned out must use less than the amount guaranteed on actual brake test; otherwise such guarantee could not be made with any degree of safety.

The engine illustrated has a brake output of 50 h.p. and is direct connected to a 30 K.W. 220 Volt D.C. generator, running at a normal speed of 425 R.P.M. It would therefore use 10,000 gallons of fuel oil per year, if operated 10 hours a day under full load for 300 days. This fuel costs on the average of 5 cents a gallon and would mean a total of $500 for annual fuel cost. This reduces the fuel-cost of current to $.005 per K.W. hour.

Construction of Generator

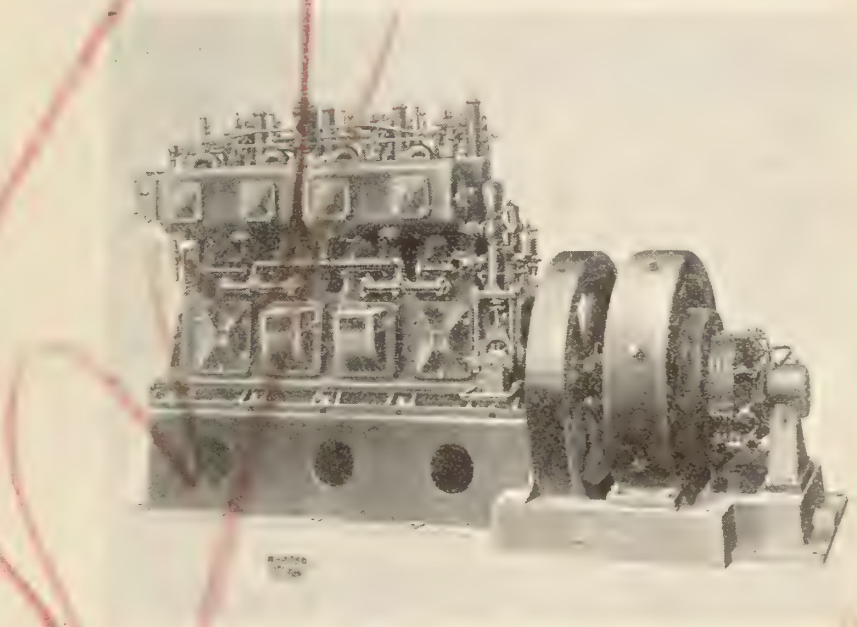
The generator used has been developed especially for this particular service by the Engberg Electrical & Mechanical Works at St. Joseph, Michigan. The armature is of the iron clad ventilated type, with laminated core, being built of electrical sheet steel, thoroughly japanned before assembling. The drum and core are provided with air ducts, permitting a thorough circulation of air through same.

Nothing but the very best double-covered magnet wire of the highest conductivity is used, and the insulation is thoroughly waterproof. A very desirable feature in connection with the armature is that it has been so designed as to eliminate a coupling on the armature shaft, the crankshaft coupling is direct connected to the armature drum, by such construction that the engine drives through the armature and not on the armature shaft. This method of construction is very substantial and makes it very easy to remove the armature—in fact this can be done without disturbing the engine in any manner whatever. Close regulation is assured by having the flywheel of the engine located close up to the armature and on the same end of the crankshaft.

The commutator is made of copper bars, insulated with the best grade of mica plate and is very heavy, thus insuring years of continuous operation without need of renewal. It is built up on a separate sleeve and bolted to the armature drum, so that the shaft can be removed without disturbing the windings. The bars are collected in a steel chuck, especially designed for this particular purpose, which is provided with large steel screws. The chuck is heated and allowed to expand, at which time screws are tightened to the very extreme. When the chuck cools and shrinks, the commutator is drawn into a perfect and lasting position.

Every part of both the engine and generator is of the highest possible grade in regard to material, workmanship and design. All bearings are extremely large and accurately fitted, thus assuring smooth and constant operation with comparatively little attention.

Both engine and generator are carefully tested and inspected at frequent intervals during the course of construction. Both are mounted on a heavy cast iron sub-base and dowelled in place, after which they are subjected to a final operating test under load.



GENERAL VIEW OF THE GENERATING APPARATUS.

BOILER EXPLODES AT FORT COULONGE

The cooperage plant of the Sutherland-Innes Company, Ltd., Fort Coulonge, P.Q., was the scene of a disastrous boiler explosion recently. A small boiler, which we understand was used for heating water for the cooperage, exploded, killing one man and injuring eight others. The dead man was not killed outright, but died later from his burns and shock. We are not in possession of any of the details of the boiler or the accident at time of writing.

TRADE ANNOUNCEMENT

The Beldam Asbestos Co., of Hounslow, Middlesex, England, have opened a Canadian branch at Toronto, under the managership of Mr. J. A. Robertson, who has just returned from England following the organization of the company's plans for Canada. A heavy stock of the well-known "Lascar" and allied brands will be carried at the Toronto house. It is interesting to know that the works at Hounslow have trebled in size and output in the last three years. The Canadian address is 19 Jarvis Street, Toronto.

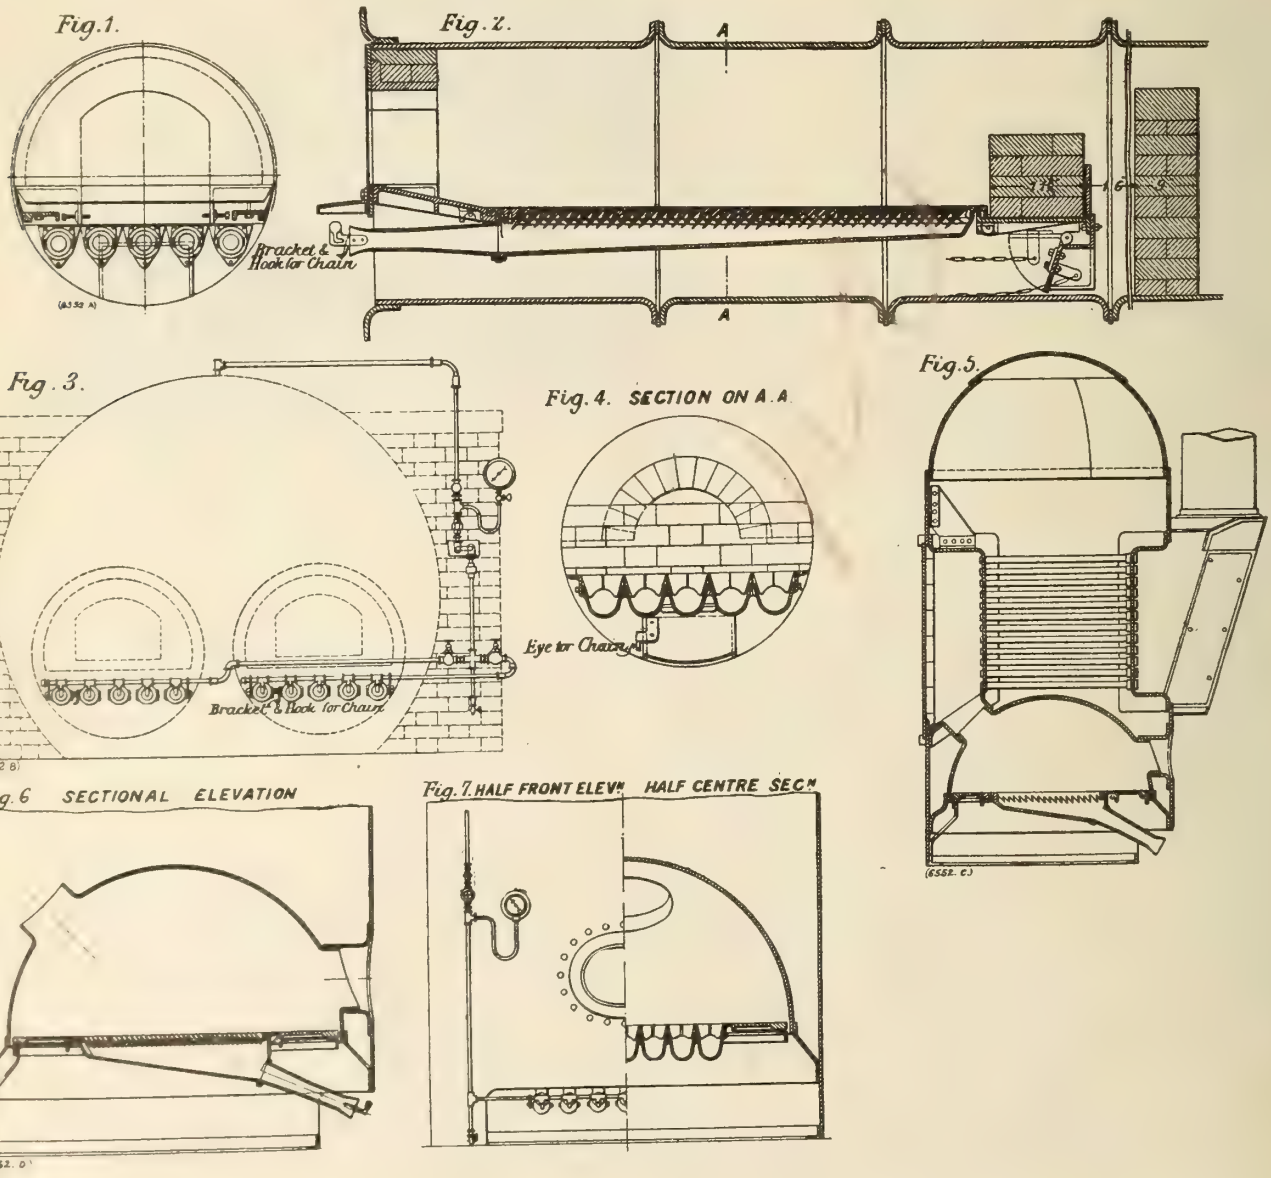
Progress in New Equipment

THE TURBINE FURNACE

The following interesting description of a new type of furnace is taken from the pages of Engineering (London). This should be of interest to steam users on this side of the Atlantic, where fuel has reached unheard of prices, and seems inclined to stay there.

The present fuel situation and the fact that there are no indications of any important fall in the cost of fuel in the future renders any appliances for utilizing the cheaper, or poorer, grades of great importance. Much has, of course, been done in various directions to accomplish this, but in many cases expensive reconstruction work is necessary before the appliances can be utilized, so that the ease with which it can be installed would appear to be not the least valuable of the features of the furnace which has been brought out by the Turbine Furnace Company, Limited, of 5, Budgerow, London, E.C. 4. The appliance has other important qualifications, however, as will appear in the course of this description. For the moment it may briefly be said that it will efficiently burn almost anything which can be described as fuel; coke breeze, slurry, small slack, cinders and similar poor fuels are being successfully utilized in many boilers to which the furnace has been fitted.

The details of the furnace will be clearly followed from Figs. 1 to 4, above, which show an installation applied to a Lancashire boiler. This arrangement consists of a series of troughs which lie side by side, and form the base of the furnace. These troughs carry the firebars. As will be seen from Fig. 2, the troughs have a cross-sectional area di-



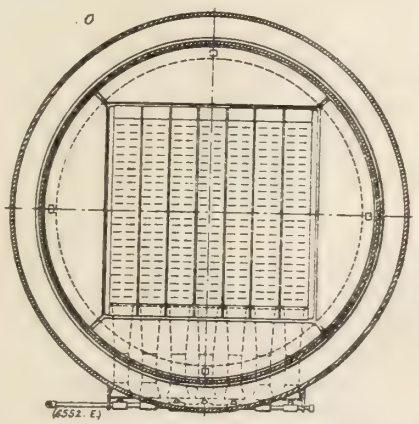
APPLICATIONS OF THE TURBINE FURNACE

minishing from the front to the back. The way they nest side by side is best shown in Fig. 4. The front of each trough forms an air injector and is fitted with a steam jet. This arrangement of troughs forms one of the special features of the furnace, and it will be clear that it results in the air supply being divided up and distributed evenly over the fire. This even distribution prevents the formation of holes and uneven burning. A further special feature of the furnace lies in the form of the fire-bars. As will be seen, these are of vee section inclined to meet the incoming air blast. It is this feature of the furnace which has given it its name of the "Turbine" furnace. The air troughs can be likened to the nozzle and the fire-bars to the blades of an impulse turbine, and it will be evident that some approach to a stream-line flow of the air from the injector up through the fire will be obtained. The arrangement should certainly cut down resistance and economize the expenditure of energy in the steam jets, and the performance of the furnace in numerous installations would appear to show the arrangement to be a very satisfactory and efficient one.

The fact that the division of the incoming air through the series of troughs breaks it up and ensures a uniform supply to all parts of the fire has already been referred to. The uniform distribution which is obtained, however, also owes much to the gradually diminishing section of the troughs and the shape of the fire-bars. The overall result of the arrangement would appear to be a uniform air pressure below and throughout the whole of the furnace. The uniformity can be well seen if a thin fire is maintained, when an even burning with an absence of holes is obtained. These special air-flow arrangements naturally tend to keep down the power required from the steam jets, and as a result a small jet only is necessary. The nozzles are of gunmetal with holes something less than 3-32 inch diameter. The holes are formed with a square shoulder near the entrant end with the result that considerable contraction is obtained, and a jet of considerably smaller diameter than the hole issues from the nozzle. To further economize the consumption in the jets the steam is superheated before being carried to them. This decreases the density and so decreases the quantity of steam used.

It is not necessary to say anything in great detail about the mechanical construction of the furnace, as its features are well shown in the illustrations. It may be stated, however, that the whole arrangement is self-contained and sits in the boiler flue without any drilling for bolts, or rivets, being necessary. As will be seen, front and back castings are provided on which the air troughs hang. The troughs are of uniform width, and in the cases of flues of greater, or less, diameter, more, or fewer, troughs are fitted. The fire-bars are comparatively small castings, and each holds the one immediately behind it in place. A special locking bar is used at the front end. The superheater is a simple U-tube arrangement fixed in the flue to one side of the boiler. Its position together with the run of the steam connections to the jets are clearly shown in Fig. 3. In many Lancashire boilers no great degree of superheat will be obtained with this arrangement, but the steam will be dried and its density lowered, which is the object aimed at.

A further point which should be mentioned is that the grate is set somewhat lower than is usual. The dead plate at the front of the furnace has a downward slope to allow of this. The idea of this arrangement is to increase the combus-



TURBINE FURNACE IN COCHRANE BOILER

tion space. Other details are the two firebrick bridges and the cleaning door operated by a chain, all of which are shown in the figures. In operation, the steam jets may, of course, be regulated to suit the fuel or the conditions of any natural draught arrangements which may be fitted. There is no tendency for the forced draught to return through the flue door, and this door may be opened at any time without the steam jets having to be attended to in any way. Owing to the form of the bars and the distribution of the draught very small fuel may be burned without choking of the bars. Very little ash makes its way through into the troughs, and what does can be removed without difficulty with a half-round scoop. An installation of the furnace applied to a Cochran boiler is illustrated in Figs. 5 to 8. These are of interest as showing the adaptability of the furnace, but it is not necessary to refer to them in detail as the arrangements are well shown in the figures.

This furnace was, we believe, introduced very shortly before the outbreak of the war, and from that time up to the present we understand some 600 equipments have been installed. This rapid advance during a period of difficulty may, no doubt, partly be explained by the ease with which the furnace may be installed and its adaptability to a wide range of fuels. In some cases an entirely satisfactory boiler plant has been dependent on supplies of a particular grade of coal. Such a state of affairs was a workable one before the war, but in the new conditions which have now arisen it has become necessary to burn fuels of poor quality or of widely differing grade, and a device such as the "Turbine" furnace is of great value. We may say that a boiler fitted with a "Turbine" furnace is employed by the Gas Light and Coke Company for the purpose of testing the steam-raising powers of various fuels. As an example of the operation of the furnace we may quote the results of a test taken by the General Electric Company, Limited, at Birmingham. The test was carried out on Galloway boilers, 28 feet long by 7 feet 6 inches diameter. An economizer was fitted, and there was a chimney 120 feet high. Midland slack of a calorific value of 9,076 British thermal units was burned. A comparative test with ordinary fire-bars and the "Turbine" furnace was made. The test extended over 6 hours and during that time the "Turbine" furnace burned 9,034 pounds of fuel against 6,272 pounds in the ordinary furnace. It evaporated 50,800 pounds of water against 25,800 pounds, giving a result of 4.34 pounds of water from and at 212 deg. F. for the ordinary furnace and 6 for the "Turbine" furnace.

A NEW COMPENSATED HEAT-METER

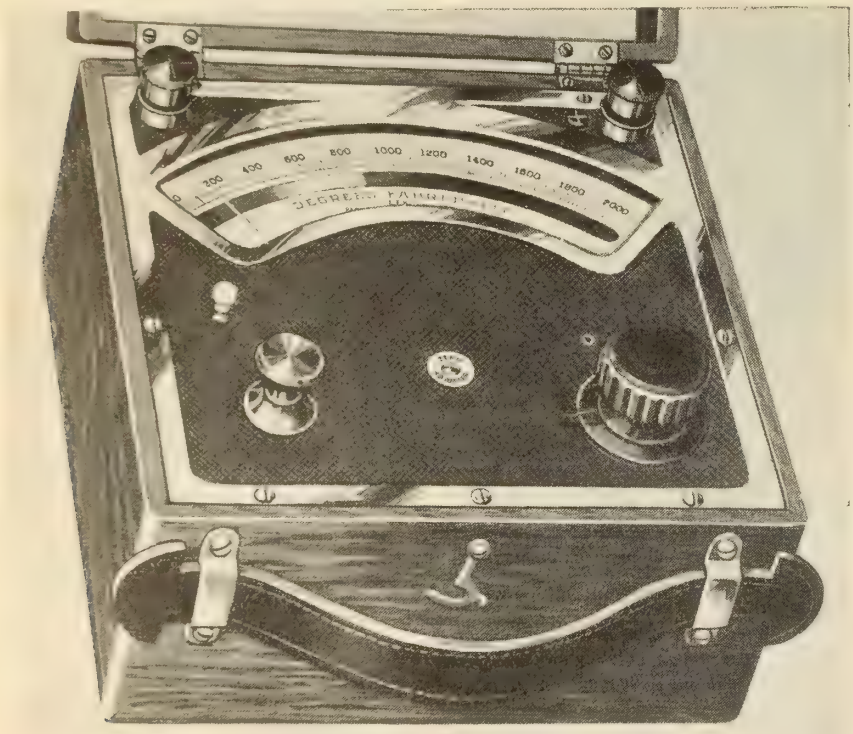
Until comparatively recently, the determination of furnace and kiln temperatures by means of thermocouples was attended with complications and difficulties which made practical men impatient, and in some instances doubtful in regard to the intrinsic value and reliability of the method.

Technical men, however, have realized from the beginning that, within certain temperature limitations, the results obtained by the use of thermocouples were not only accurate, but could be made "direct reading," provided that the thermocouple be connected with a galvanometer which would indicate the actual value of the e.m.f. obtained by heating.

On first consideration, this problem did not seem difficult of solution, since it is an established fact that the e.m.f. or voltage of a thermocouple bears a direct relation to the difference in temperature between its hot and cold ends. It is also true that the movable coil of a millivoltmeter will be deflected to an extent which is directly proportional to the e.m.f. of the thermocouple. Therefore it would seem the simplest operation imaginable to connect the thermocouple and the instrument together by means of insulated conductors, figure the scale in temperature values and regard the problem as solved.

Unfortunately, however, we have also to contend with factors which cannot be ignored if accurate results are required; namely, line resistance, thermocouple resistance, and the resistance of the indicator itself, because, to be pre-

cise, a direct current millivoltmeter actually is not a millivoltmeter at all, except in name, but is a milliameter or current indicator. All instruments of the d'Arsonval type depend primarily upon current for their operation and the extent of the deflection obtained with any given current is established by the intensity of the magnetic field, the controlling force of the springs, and the number of convolutions or ampere turns in the movable coil, and not by a remote e.m.f. Therefore, if the conductors which carry the current from the source of e.m.f. to the terminals of the instrument do not have a negligible resistance, then, in accordance with Ohms' law there will be an appreciable fall of potential along the line, with the result that the movable system will receive a diminished current and therefore



GENERAL VIEW OF THE HEATMETER.

be low in its readings. To reduce such errors to a minimum, it is desirable that the instrument resistance be as high as possible, so that the line and thermocouple resistant may be proportionately insignificant. For instance, if the resistance of the millivoltmeter is 300 ohms, and the resistance of the line (A) and thermocouple (C) is 3 ohms, the current through the circuit will be reduced ½ of 1 per cent. instead of 1 per cent., and the instrument indications will be 1 per cent. low. Figured in degrees Fahrenheit, this would mean an error of approximately 14 deg. in 1400 degs. Fahr. if a thermocouple were used.

The advantage of high-resistance instruments, therefore, becomes evident. For instance, if the pyrometer has a resistance of 600 instead of 300 ohms, and the line resistance remains the same, an error of 3 parts in 600 will result or only ½ of 1 per sent. instead of 1 per cent., or about 7 deg. Fahr. in 1400 deg. Fahr.

Until within the last five years it was customary to use a so-called low resistance pyrometer to measure the current from the thermocouple. These instruments had from 2 to 5 ohms internal resistance and were naturally materially affected by the external resistance of the thermocouple and leads. In the past few years high-resistance pyrometers have been almost universally adopted. These instruments have an internal resistance of usually from 300 to 1200 ohms. The higher the resistance naturally the less effect on the readings due to variations in line resistance, but will increase in internal resistance; something has to be sacrificed, and usually control or torque is weakened. In consequence, the instrument is not as substantial or dead-beat, and, due to the use of lighter springs is more apt to be affected by spring fatigue.

It has been found by trial that an instrument of medium resistance (about 500 ohms) can be produced in a satisfactory and substantial form, but an instrument of this class is necessarily affected in its indications when leads of considerable length are employed. Material variations in the length of thermocouples are also a source of error, as well as the introduction of compensating leads. When compensating leads are employed, as well as long wires, in connecting the thermocouple with the instrument, it is a common practice to reduce the resistance of the instrument in order to offset the effect of line resistance. This is at best a method of doubtful value, since it interferes with checking the scale by comparison with a standard, and does not compensate for changes in the resistance of the line or thermocouple, due to variations in temperature.

Various devices and attachments have been made for use in connection with indicating and recording millivoltmeters and pyrometers, by means of which the instruments will remain direct reading, and at the same time be compensated for external or line resistance. Inventions of this class range all the way from a simple step rheostat connected in series with the "dead" resistor of the instrument, to the elaborate and complicated apparatus employing the substitution and deflection methods, the potential of the thermocouple being first balanced against another potential derived from a dry cell, and after an intermediate operation and on intercomparison of deflections, the effect of line resistance is finally balanced out by means of a rheostat, and direct deflections are obtained from the thermocouple current.

It remained for two physicians, Paul D. Foote and T. R. Harrison, of the Bureau of Standards, Washington, to offer an invention of theirs, which, incorporated in a Brown pyrometer, eliminates the effect of line and thermocouple resistance by means of an operation which is so simple that anybody can use the instrument and obtain accurate results.

This improved heatmeter will unquestionably appeal to the practical man who wants results and does not care especially how the instrument functions provided its indications can be relied upon.

In testing with this apparatus all that is necessary is to connect the thermocouple with the instrument binding posts in the usual manner, press a button, turn a knob, and take a reading, which will be the correct e.m.f. of the thermocouple at its hot end, even if the line is miles in length. In fact the line may have as much as 15 ohms resistance. The Brown Instrument Company, Philadelphia, are the manufacturers of this equipment, and the accompanying illustration shows one form of the complete instrument. As will be seen, the accessory details incorporated into the instrument do not decrease its portability and convenience nor increase its size.

AN ANCIENT STEAM ENGINE

The closing up of an old dry dock at West Harbor, Greenock, brings into prominence the old pumping engine, which has been in use for the past 135 years, and is still in good working order. The graving dock was built by James Watt in 1785, and the engine was also built by him, and has been there ever since. The engine is fitted with the Watt governor for controlling speed by opening and closing the throttle, differing but slightly in design and nothing in principle from the throttle governors used today. The fact that Watt built the dock brings back to memory the fact that he was a civil engineer, and in that capacity built the first dry dock in Scotland, at Port Glasgow, in 1762, and the dock is still in use.

The Operators' Point of View

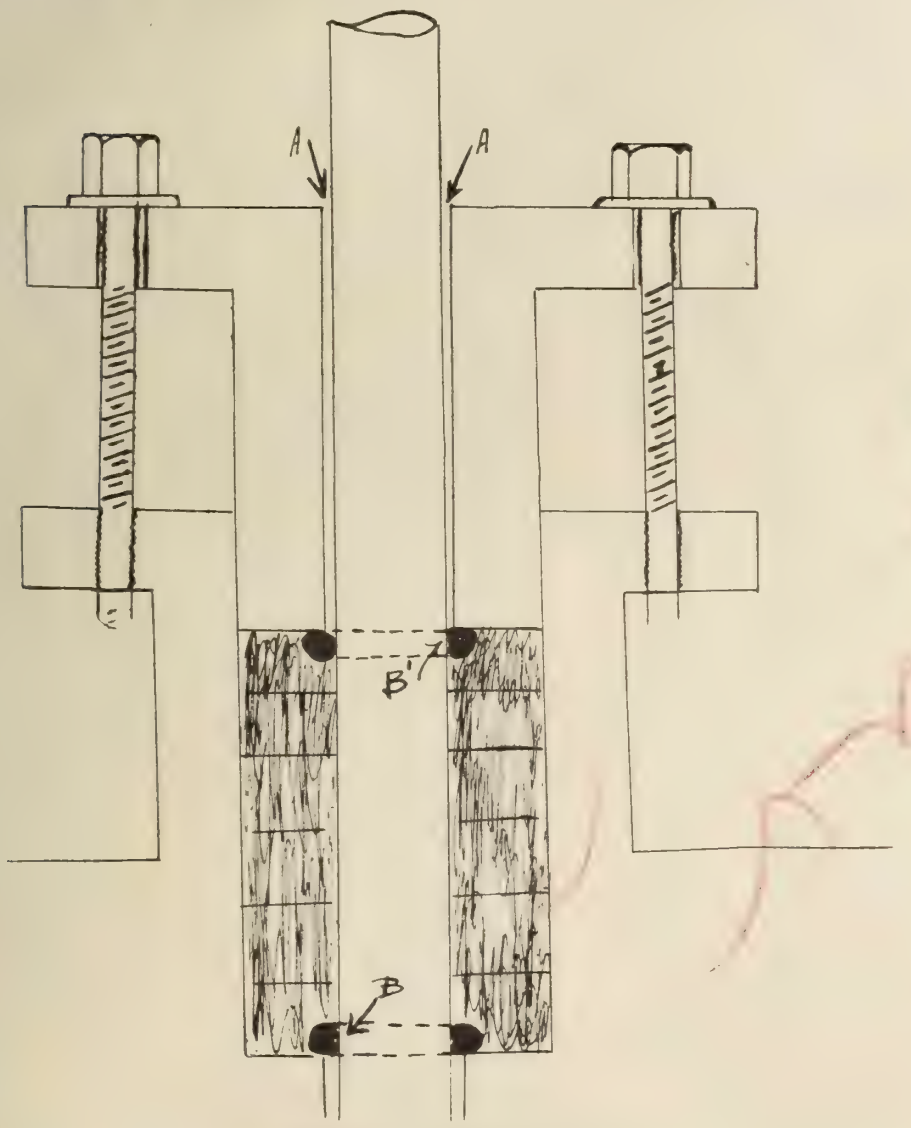
FOR WORN RODS

It is a common trouble for a rod to become worn, also the packing follower and the bottom hole in the packing box may be enlarged to a diameter greater than the rod. When these things come to pass much trouble is made. The packing around the rod becomes worn and steam or water finds its way through, making it necessary to be continually tightening up on the follower nuts. Numerous remedies have been suggested, most of them having good points.

If the rods are small, such as valve rods on the average power plant duplex feed pumps, the trouble can be practically eliminated by forming a ring around the valve rod, with ordinary wire solder, such as electricians use, allow it to be on the bottom of the box, fill the box with packing and use another ring at the top as BB in the sketch.

If the rod is of larger diameter and rapid moving, something more substantial must be used. Nothing is better than a pair of rings made from soft copper solid cable. The rings can be formed on the rod, using a piece of wood to knock them into shape. Experience would seem to teach that such circular rings work out better than flat rings.

JOHN JAMES.



MAKING UP WORM NECK BUSH

HEIGHT HOT WATER CAN BE LIFTED

By C. C. Warren

(Copyright. All rights reserved)

Hot water cannot be lifted to the same heights as can cold water. In drawing boiler-feed water from a hot well, the boiler-feed pump may be required to "suck" or lift the water to the location where the pump is situated. For each temperature of feed water there is a maximum height to which it can be thus lifted. Water at ordinary temperatures can be lifted a distance of from 32 to 33 feet. (Theoretically, the maximum lift distance at the sea level is 33 1-3 feet.) If an endeavor is made to lift the cold water farther than the heights just specified a vacuum is established and the water cannot be raised. In practice, because of leaks, imperfect pumps, imperfect valves, pipe friction and other conditions, the possible lift for cold water is usually much less than 30 feet. Under ordinary working conditions the greatest possible cold-water lift is usually assumed to be about 20 feet. But if the water is hot it vaporizes readily when suction is applied. This limits the possible lift. It is customary to so arrange the feed pump that the water will, where the temperature exceeds 120 deg., flow into it by gravity.

Following is a table indicating the maximum theoretical lifts at various temperatures. Actually, the heights of lift indicated can not be attained. The decrease will be determined by pipe friction, leakage and similar effects. In practice, lift values of from possibly 60 to 75 per cent. of those tabulated may be effected.

FAIRBANKS-MORSE

A National Institution of Mechanical Service

IN Canada, as in every country in the world, there are names which, through years of service, have warranted national confidence and good-will. In the Canadian world of mechanical and engineering efficiency there is one name which enjoys the distinction of leadership. Its prestige carries through the entire coast-to-coast chain of sales offices and warehouses into every city, town, and hamlet.

Fairbanks-Morse products mark the farmer, the manufacturer, the artisan, and all users as careful and practical buyers of mechanical goods. The Fairbanks-Morse 100% quality seal is the buying guide for the consumer—the guarantee of satisfaction.

The Canadian Fairbanks-Morse general catalogue is a reference of what is standard in design and practice in mechanical goods. This book lists the largest variety of scales, valves, steam goods, oil engines, pumps, electrical machinery, machine tools, woodworking machinery, transmission appliances, railway contractor's and machine shop supplies ever published in Canada in one book. Your copy will be sent on request.

CLASSIFIED ADVERTISEMENT SECTION

TWO CENTS A WORD, including the "Power House" box numbers; minimum charge is $1.00 per insertion, for 50 words or less, set in 6 pt. type. Each figure counts as a word. Display ads., or ads. set in border, are at the card rates.

GOOD INVENTIONS

ENCLOSED LIQUID FUEL COMBUSTION APparatus capable of generating intense heat in pipes and confined passages for heating parts of internal combustion engines and for other uses; spark ignited; blower operated. Patented October 8th, 1918. Can be inspected at and for sale by H. W. Petrie, Limited, 131 Front St. W., Toronto.

EMPLOYMENT DESIRED

STATIONARY ENGINEER, SECOND-CLASS, requires position; thoroughly experienced with water-tube and return tubular boilers, Corliss and all classes of stationary engines compressors, electric motors and generators; heating systems and hydraulic. Apply, mentioning "Power House," to No. 67062, A. Wright, 298 Bathurst St.

MACHINIST—WITH DRAUGHTING EXPERIence, wants work of any kind. N. Ryckman, No. 174372, 5 Foxley St. Phone Parkdale 3254w. Mention "Power House."

ENGINEER—SEEKS POSITION. ALL ROUND steam and motor experience; British Board of Trade certificate. Apply, mentioning "Power House," to Herdman, 9 Tecumseh St., Brantford, Ont.

RETURNED SOLDIER — EXPERIENCED painter, electrician and elevator operator, or other suitable employment; desires work at once. Apply mentioning "Power House," to Pte. (163466) Ira Charles Winckler, 83 Carlton St., Toronto.

RETURNED SOLDIER WANTS WORK—ANY kind; used to steam heat boilers. Apply, mentioning "Power House," to W. Greenfield (33065), 34 Brock Ave., Toronto.

RETURNED SOLDIER. CHAUFFEUR-MECHanic, must have work. Truck preferred. Reliable, steady, married. Reference. J. Koster, No. 195289. Phone Park. 7758. Mention "Power House."

BELTING

4½—4-PLY NEW CANVAS STITCHED BELTing at 30 cents per foot. We carry a complete stock of belting, pulleys and mill supplies. Apply, mentioning "Power House," to N. Smith, 138 York St., Toronto.

LEATHER AND RUBBER BELTING, USED, but in good condition; at about half new price. Apply, mentioning "Power House," to Tarshis & Sons, 400 Front St. East, Toronto.

WE HAVE A QUANTITY OF NEW RUBBER belting to sell at less than half price; will ship C.O.D., subject to inspection; new circular saws, good second-hand leather and rubber belting, wire cable, vises, chain blocks, garden hose, steam hose, rubber packing; send us your requirements; our quotations will surprise. Apply, mentioning "Power House," to The York Belting Co., 115 York St., Toronto, Ont.

SITUATIONS VACANT

WANTED—A1 GENERAL BLACKSMITH FAMiliar with mine and mill work; permanent position. Apply, mentioning "Power House," stating experience and wages wanted, to Moose Mountain, Ltd., Sellwood, Ont.

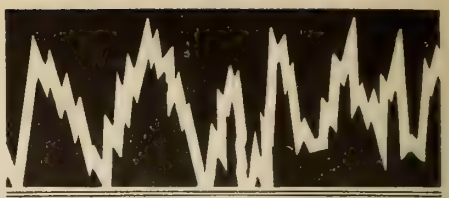
EQUIPMENT

THE JOHN INGLIS CO., LTD., ENGINEERS and boilermakers. Write us for prices. 14 Strachan Ave., Toronto. Mention "Power House."

WE BUY IDLE EQUIPMENT OR MACHINery; call or write. Apply, mentioning "Power House," to H. W. Petrie, Ltd., Toronto.

GRATE BARS

ALL STYLES TO ORDER—PROMPT DELIVery. The E. T. Lansdowne Foundry Co., 37 Niagara St., Toronto. Mention "Power House."



A Regulator that REGULATES!

If you could actually *see* the temperature fluctuations that take place with many so-called regulators, the result would be similar to the zig-zag lines shown above. This is not temperature regulation! But when you consider the complicated construction of the average regulator, and that it operates by such uncertain mediums as water, compressed air or electricity, the wonder is that the variations are not even greater.

SARCO

Temperature Regulator

has no complex mechanisms or other unreliable factors. Its very simplicity insures positive operation.

It is entirely self-contained and self-operated. Requires no outside force such as air compressors, water supply or electricity. Has no leather or rubber diaphragms or other perishable parts.

Its positive and dependable action makes Sarco the favorite regulator for delicate manufacturing processes, as well as for room control. Suitable for operating steam, water and gas valves.

Costs less than others to start with and less to install. Costs nothing for upkeep.

Sold on 30 days' trial with the privilege of return if you are not satisfied. Write nearest branch for Booklet J-52.

Carrying The Peak On Any Kind of Fuel

A difficult Problem was solved at the Spicer Mfg. Corp., South Plainfield, N.J.

Four boilers can easily carry heavy overloads and maintain the steam pressure at 175 lb. gauge regardless whether bituminous, straight anthracite or a mixture is being burned by their six

DETROIT "V" Type STOKERS

Four of these stokers (at the left) were installed under the 150 horsepower boilers in 1916. Their satisfactory performance in burning the poor quality coals available at that time, resulted in a repeat order for two additional Detroit Stokers (at the right) with Detrick Flat arches for the 300 horsepower boilers that were installed in 1918. The plant was designed by Henry R. Kent & Co., Engineers of New York City.

Detroit "V" type Stokers save coal and labor. They will burn low quality coals smokelessly on natural draft up to 200% boiler rating. Constantly increasing repeat orders are indisputable evidence of satisfactory performance under widely varying operating conditions.

Consultation with our engineers regarding your specific combustion requirements is invited. Catalog "P" gives full details. Write.

SAVE COAL

Republic

CO_2 RECORDERS

Less Worry—Less Expense

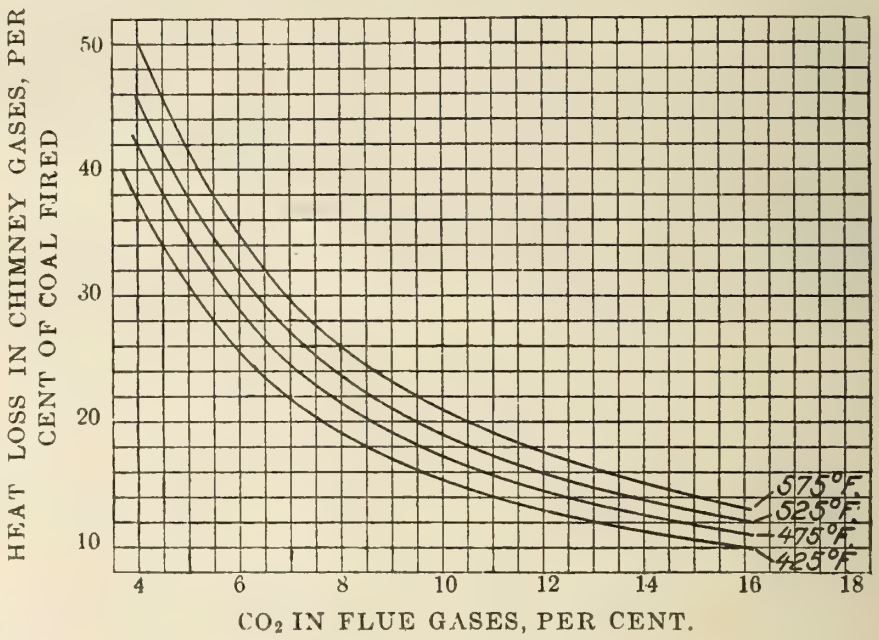
HAVING the CO_2 Recorder as a guide, the fireman or operator realizes that it is less work and worry to produce a given amount of steam with a good fire than with a poor one. Since it is always necessary to produce the required amount of steam for operation, he will welcome the possibility to produce the necessary amount of steam with the least possible amount of energy and **expense.**

The **Republic** CO_2 Recorder has been developed to operate continuously under all boiler room conditions. This enables the operator to observe the conditions of combustion at all times and to obtain the **highest efficiency** from his furnace.

THE chart shown here demonstrates the relation between the percentage of CO_2 in the flue gases and the heat losses through the smoke stack, showing the importance of observing and recording the CO_2 contents in the flue gases.

These curves were prepared by the Bureau of Mines at Washington, and we believe that they are absolutely reliable; the most up-to-date and exhaustive that it is possible to find.

By a reference to this chart it will be seen how the reduction of CO_2 shows the tremendous wastes that are going on in every plant to-day.



What is your percentage of CO_2? If you do not know, then you should know. If you do know, then refer to this chart, find out what your percentage of waste is, and the result, we feel sure, will be that the average CO_2 carried in your plant will be increased at once.

Aside from its other advantages, the fuel you can save with a Republic CO_2 Recorder should decide you to at once investigate its possibilities in your plant. Let us get together on this question!

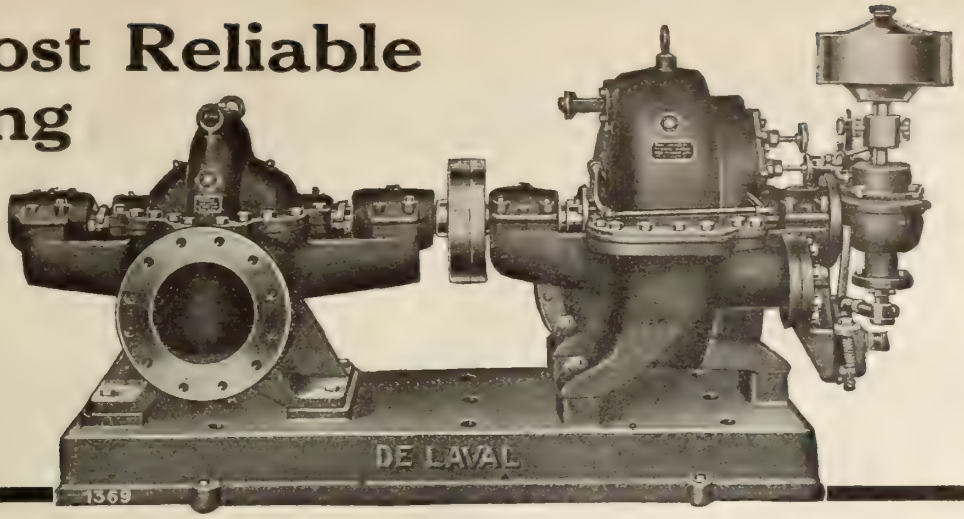
The Most Reliable Pumping Unit



THE De Laval centrifugal pump driven by the De Laval steam turbine represents the simplest, most reliable, and most economical method for handling liquids. There are no valves and no rubbing surfaces, except the bearings, which are automatically oiled. All internal working parts are accessible upon lifting the casing covers, and without disconnecting piping. The unit occupies only a small fraction of the space taken by a reciprocating pump, and requires only light foundations. Little attention is required further than to see that the oil wells are kept filled. The exhaust steam is free of oil and can be used for heating or industrial purposes.

If you are interested in pumping apparatus, ask for our new Bulletin B-100

What Will Santa Claus Bring Our Politicians ?

"SANTA'S POLITICAL STOCKING" is the title of J. K. Munro's feature article in MACLEAN'S December 15th issue. Mr. Munro thinks old Kris Kringle should bring Premier Meighen a "cap that will pull down over his ears, so that he can't hear what his Cabinet colleagues are saying about him"; a hobby horse for Crerar; a tin sword for Ballantyne; a "white plume" for Lapointe; a case of grape juice for Rowell, and a pair of long trousers for Mackenzie King.

Mr. Munro also sizes up the East Elgin farmers' victory, and lets you know its real significance.

Dr. Wilfred T. Grenfell, C.M.G.

THE famous physician of Labrador has contributed a striking piece of graphic fact-fiction for the Christmas issue—"Deeds of 'Derring Do'." which describes the brave fight waged by Skipper Loveday, his crew and wife—in the dismantled Silver Queen. They expected to find a watery grave that Christmas week, but the wife's dauntless spirit put so much courage into the men that they won a fearful fight against the December gales.

Christmas Issue of Maclean's, December 15th

"THE EMANCIPATION OF POLLY MacCRAE"
By F. B. M. Collier.
The so-human story of two spinster sisters in Old Ontario and how the crippled one won a husband.

"THE JEST OF CIRCUMSTANCE"
By Gertrude Arnold.
Phyllis lands in a Canadian city, fresh from England, and there is no fiancé to meet her. The girl ultimately finds happiness just as the Christmas Carols commence—but how?

"OUR GOLDEN FLOOD ROARS EAST"
By Nicholas North.
Every few minutes a train loads up at one of our many mammoth grain elevators, taking our wheat to the seaboard.

"THE CITY OF PERIL"
By Arthur Stringer.
The largest instalment yet published of this sensational dramatic serial of Bolshevistic plotting in New York.

"—AND ALL POINTS NORTH."
By Nellie L. McClung.
A gripping story of the pioneer men and women of the Peace River country—many even out of the reach of railroads, telephones and doctors. Read what trained nurses are doing in the pioneer settlements.

"OF CHRISTMASES AND GOVERNORS"
By Colonel George Ham.
The "Colonel" has spent Christmas in some peculiar places. His experiences form the foundation of a great story. Also, Col. Ham tells of the human side of some of our Governors-General.

"WHO GETS OUR PAPER PROFITS?"
By Agnes C. Laut.
The real facts of our paper, pulp and sulphite products, and some information as to where the biggest slices of the melon go.

"THE YULETIDE GLOW"
By Charles Christopher Jenkins.
What converts Scrooges into human beings, 'round about December each year? Get in a crowd with "Jenk" and you'll find out.

"BUTTERED SIDE UP"
By C. W. Stephens.
The hero of this story loses his job a few days before Christmas. But he doesn't lose the girl, and lands a real job Christmas Eve.

"ORATORS I HAVE ENJOYED"
By "Margot" Asquith.
The wife of the ex-Premier tells what she thinks of Lloyd-George, as an orator, and others.

QUALITY YORK SERVICE

York Uniflow Engines for Ice Making and Refrigerating Plants

One of the most important considerations in an Ice Making or Refrigerating Plant is the type of prime mover. An economical ice plant should have a dependable motive power, and one which will maintain a reasonable economy when called upon to operate over a range of from ¼ to 1¼ times the normal load.

It is well known among refrigerating engineers that the best compressor economy is obtained when evaporating pressures are carried as high, and condensing pressures as low, as possible. Even well balanced plants are forced to meet extreme seasonal conditions, with evaporating pressures varying from 20 to 30 pounds and condensing pressures from 85 to 225 pounds. These pressure variations and seasonal requirements of the Trade impose load factors of corresponding variation on the engine operating the compressor.

The Uniflow Steam Engine presents itself as the best solution of this difficulty

The ANDERSON
PRESSURE OIL FILTER

THE high price of oil is serious; and yet fully 50 per cent. of the oil bought in this country is wasted—lost on wipers.

By placing drip-pans beneath the machinery and passing the oil thus collected through an Anderson Pressure Oil Filter, this waste can be practically eliminated.

The Anderson Filter cleanses and purifies the oil by a treatment identical to that of the refiners. It comes from the filter in a pure, clean state, fit for the finest bearings.

Write for fuller particulars of the Anderson Pressure Oil Filter.

The V. D. Anderson Co.

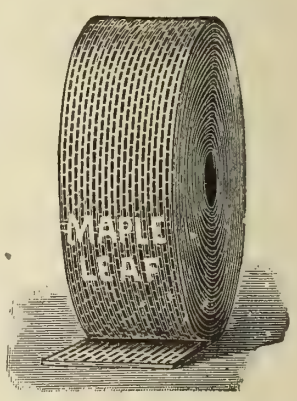
Dominion Belting Company, Limited
Hamilton, Canada

Sole Manufacturers of the celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing.

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.



"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

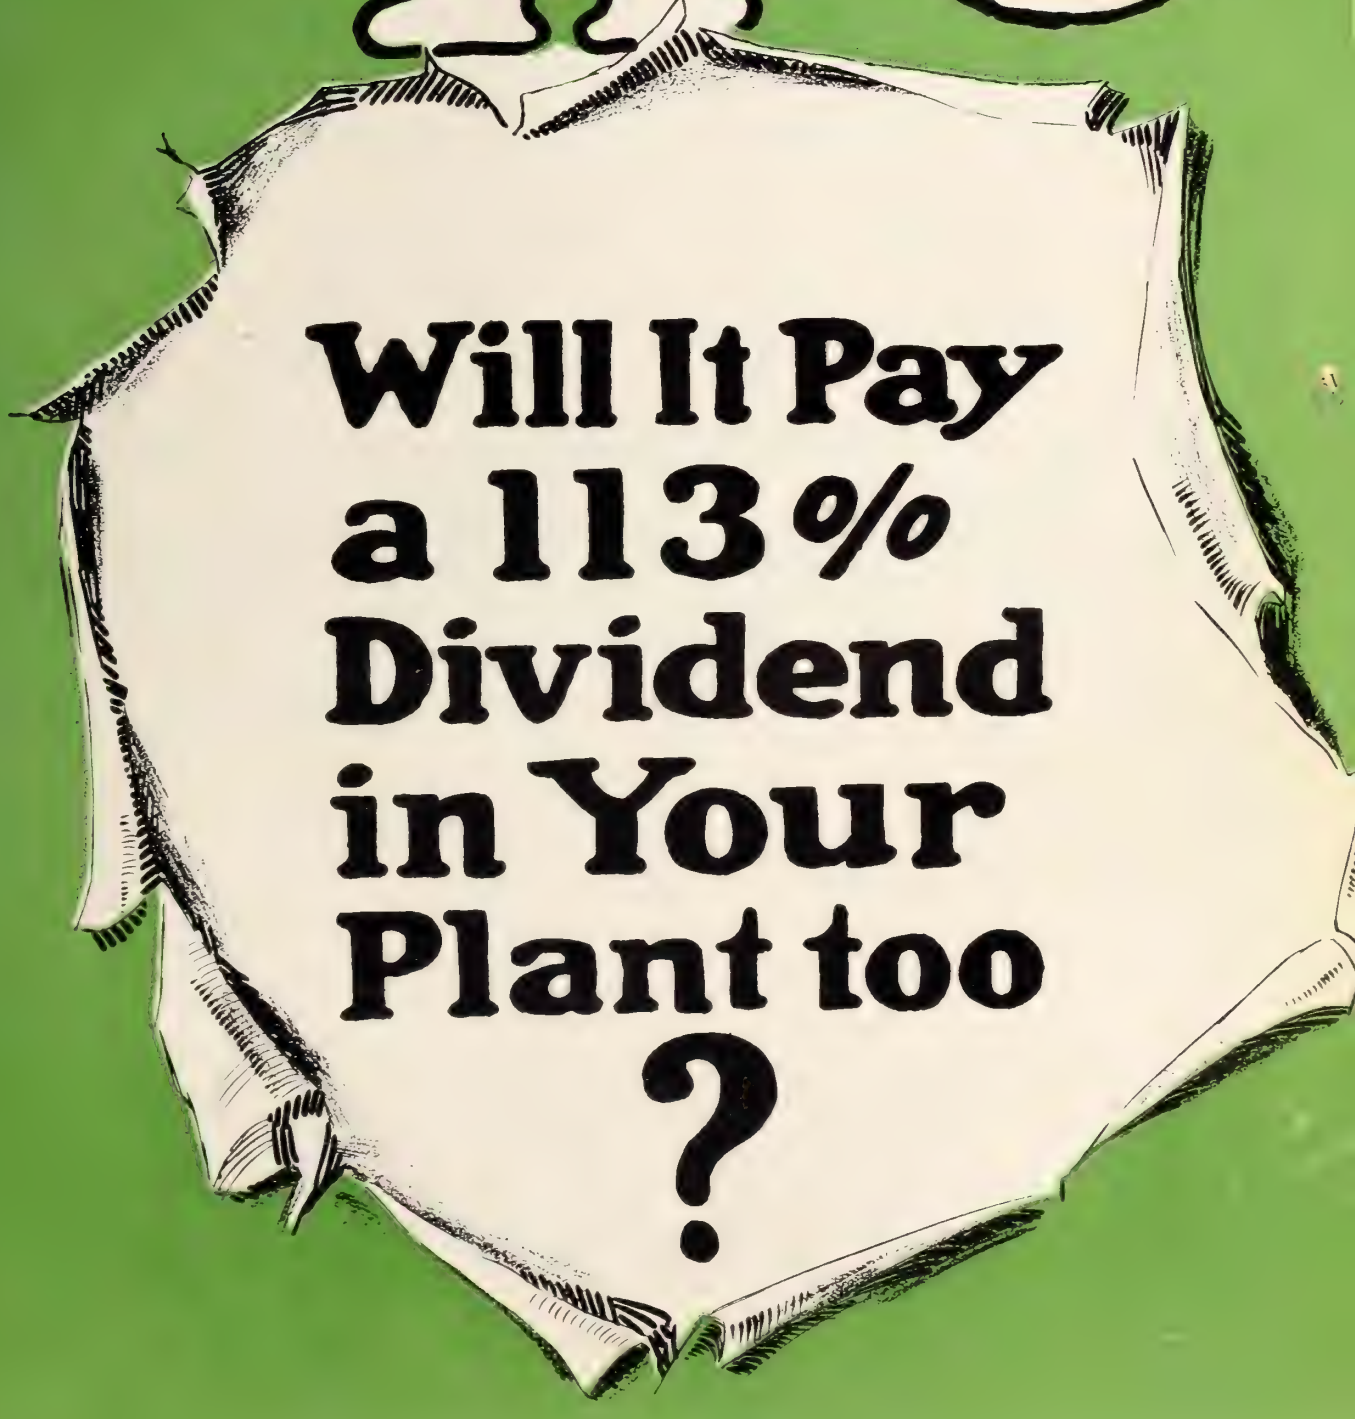
Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber or Balata, as well as our own make.

Write us for prices, and if desired we will be pleased to furnish samples and further information.

A trial order will convince you of their utility.

DOMINION BELTING CO. Ltd., Hamilton, Canada-Quebec Branch: 51 Duluth Bldg., Montreal

Jones "A-C"



Will It Pay a 113% Dividend in Your Plant too ?

Is This

Hand Fired—

Labor: 5 men per shift	$ 18,000.00
Coal: 4½ tons per B.H.P.	121,500.00
*Annual Cost	$139,500.00

*Assuming a boiler plant consisting of six 250 H.P. boilers (a plant of average size) operated 24 hours a day, 300 days a year. One boiler held in reserve. Labor calculated at 50 cents per hour for the two 12 hour shifts. Coal estimated at $6.00 per ton.

There Is Only
Yet It Means an Annual

The two plants compared above would be alike but for one big exception —Jones Stokers.

The cost of installing Jones Stokers in the plant now hand fired would be $17,000.00—and the saving (repairs and depreciation liberally taken into consideration) would be $19,250.00 yearly.

Think of it, Canadian power users; 113% on the investment. What equipment can you install that will yield as great a return?

This vast economy is not the only advantage to be gained by Jones Stoker firing. There are many more that pay a separate dividend in increased production and **satisfaction.**

Your Plant?

Stoker Fired—

Labor: 3 men per shift	$ 10,800.00
Coal: (12% saving)	106,900.00
Depreciation: (10%) (a liberal estimate)	1,700.00
Repairs: (5%) (a liberal estimate)	850.00
†Annual Cost	$120,250.00
Annual *Saving*	19,250.00

†Assuming same plant capacity, fuel and labor costs as in hand fired plant with which comparison is made.

One Difference
Dividend *of* 113%

Boiler capacity is increased 50 to 100%. Increased load demands, sudden plant expansion, the call for quick steam and continuous operation will not necessitate an increase in the size of the boiler plant.

Such is the flexibility, the **reserve power** of Jones Stokers, "A-C" and "Standard."

And when the man with the shovel is replaced by Jones "A-C" Stokers, the engineer will know the feeling of security that comes from ability to burn every grade of coal—always the cheapest coal available—thereby making an additional saving, a saving not taken into consideration in the cost comparison above.

The next page outlines the comprehensive engineering service now placed at the disposal of Canadian plants.

An Engineering Service That Goes Beyond Mere Stoker Building

Designing and building a mechanical stoker is one thing—properly installing it another. Both are vital elements of stoker success.

The mechanical superiority of the Jones Stoker has been proved beyond question, but Jones engineering goes farther than merely building a super-stoker. The reorganization of this Canadian company permits following out the Jones standard of maintained service to a greater extent than ever before.

To the wealth of experience gained in installing the Jones Stoker in hundreds of prominent Canadian plants, has been added the engineering resources of the Under-Feed Stoker Company of America. The new company offers a service that begins when plans are taking shape and does not end when the stoker installation is completed.

Every Jones salesman is a trained engineer willing to make a survey of your firing problem and recommend a solution—without implying any obligation.

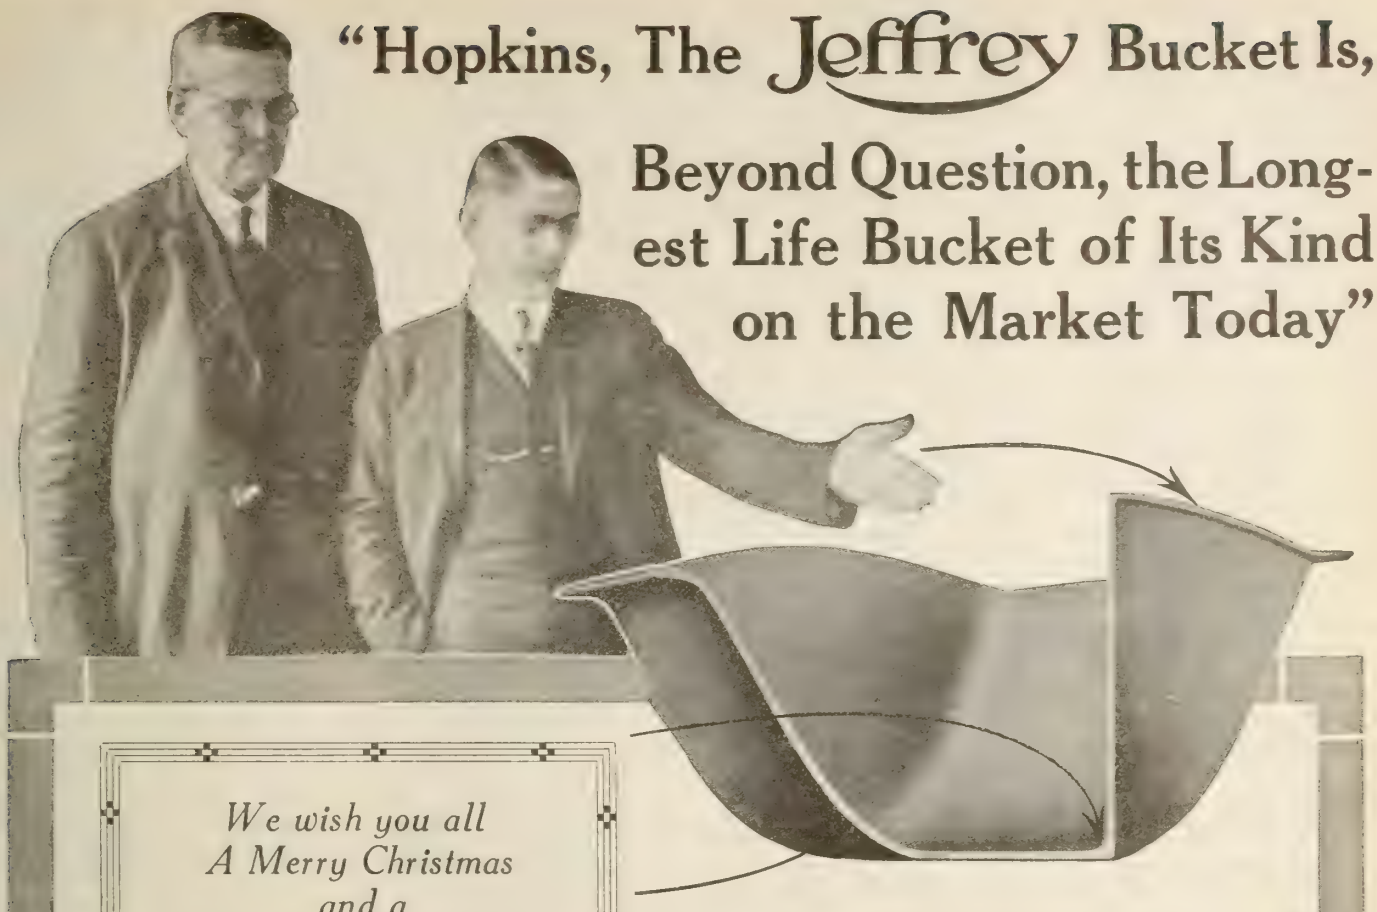
"Hopkins, The Jeffrey Bucket Is, Beyond Question, the Longest Life Bucket of Its Kind on the Market Today"



We wish you all
A Merry Christmas
and a
Happy and Successful
New Year

"THE efficient bucket design of The Jeffrey Pivoted Bucket Carrier is one of the most important improvements that have been responsible for its remarkable success.

"The Bucket outline gives the greatest capacity for complete discharge of materials, with minimum shock to the conveyers as a whole, and with minimum wear to the Bucket's Hardened Tripping Cams.

"The bucket section plainly shows surfaces, edges and corners which have been re-inforced where long experience has dictated. You will notice too, that there are no obstructing rods running across the buckets."

Catalog No. 210-4 completely illustrates and describes the Jeffrey Carrier and features many important installations.

Let us send your copy.

Showing ease with which Plibrico is laid in place.

PLIBRICO SAVES COAL

by making your furnace air and gas-proof.
Plibrico can be installed by inexperienced labor. Plibrico also makes an excellent material for baffle construction and repairs.

A High Grade Refractory

Shipped in steel containers only. Warehouse stock carried in principal cities for immediate shipment.

Write for book on furnace building.

Manufactured exclusively by

JOINTLESS FIRE BRICK CO.

Offices and Factory: 1130-1150 Clay St., Chicago, Ill.

Tycos

TEMPERATURE INSTRUMENTS
INDICATING • RECORDING • CONTROLLING

In hundreds of power plants Tycos instruments meet the ultimate test—unusual service. The strength and the mechanical worth of the instruments — the skilled advice given in their application all mean the satisfactory solution of extraordinary as well as ordinary temperature problems.

Angle and Straight Stem Thermometers
Indicating and Recording Thermometers
Hydrometers Hygrometers
Engraved Stem Thermometers
Temperature and Pressure Regulators Pyrometers
Vacuum, Pressure and U Gauges.

Let Tycos catalogs and Tycos engineers be your guides in temperature needs. Request literature and specific advice—no obligation.

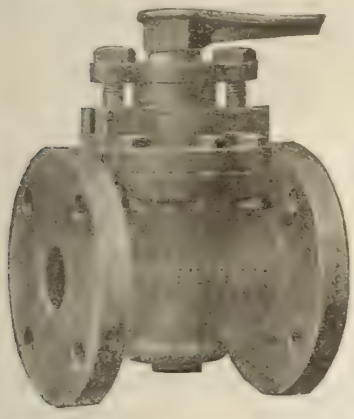
HOMESTEAD
Quarter-Turn Valves

—simplicity

Simplicity is the dominant feature of Homestead Valves. Simplicity of design and simplicity of construction. This is why they are so effective and dependable.



Instead of the six to ten turns of wheel necessary to ordinary globe or gate valves, a quarter-turn only is required to change a Homestead from absolute tightness to a straight, unobstructed flow, or vice versa.

Made in Straightway, Threeway and Fourway patterns for air, steam, water, oil, gas and acids.

Homestead Valve Mfg. Company

Homestead, Pa.

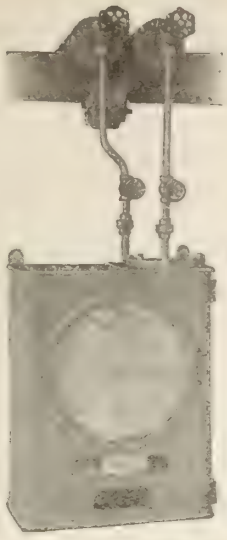
Power House
Solves the Problem

It is a dominating factor in maintaining power plant efficiency in equipment and service.

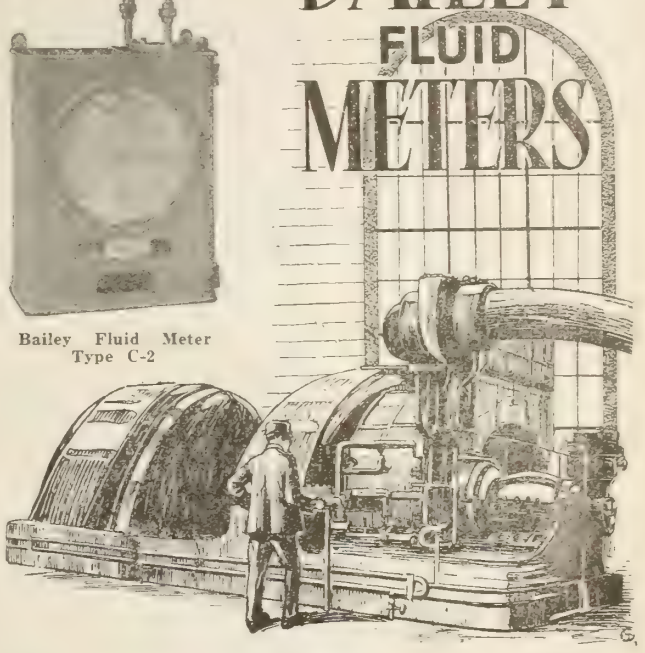
Every issue teems with advertising and editorial matter of a character that will keep YOU right up to the minute in power plant knowledge.

Two Issues per Month
Twenty-four per Year

$2.00 PER YEAR — Every Power Plant employee should read Power House



BAILEY FLUID METERS



Bailey Fluid Meter Type C-2

Accurate Measurement of All Consumption

Bailey Fluid Meters enable you to continuously check the steam flow to your turbines, auxiliary power drives, heaters, evaporators, heating kettles, heating systems, drying coils, kiers, vacuum pans and all other process work, and keep you accurately informed of the steam consumption of every unit using either live or exhaust steam.

Bailey Meters are equally dependable for measuring hot or cold water, air, gas or other fluids. Made in types to meet all conditions.

Bulletins upon request.

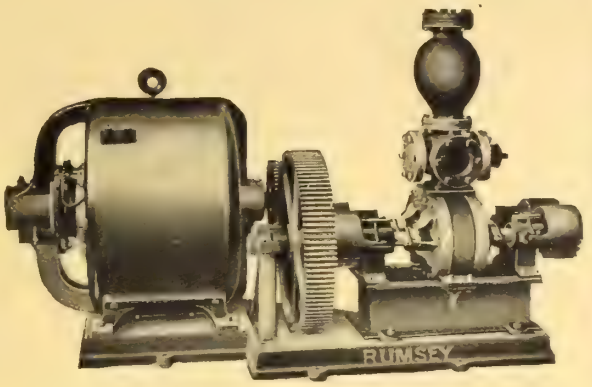
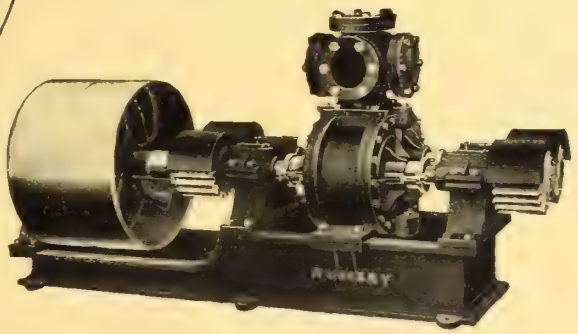
WM. B. SCAIFE & SONS CO. PITTSBURGH, PA.

RUMSEY ROTARY PUMPS

SENECA FALLS, NEW YORK

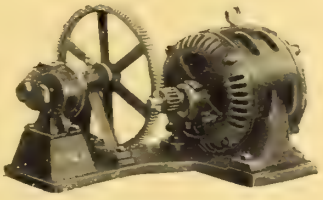


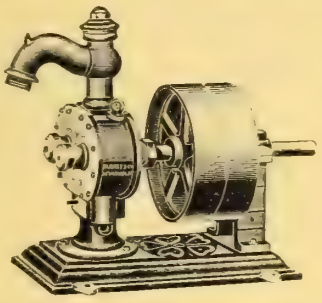
Rumsey Electric Rotary Fire Pump. Designed for general service as well as fire duty. For fire service, 100 pounds pressure is recommended and for general service 75 pounds.



Rumsey Power Rotary Force Pump. Designed for water supply, oils or special liquids for elevations up to 170 feet and pressures up to 75 pounds. A moderately-priced pump of large capacity.

Rumsey Rotary Power Force Pump. A light duty machine designed for returning oil to reservoir from drip pan, also for pumping lubricants for cutting tools, lathes or other light work where a small pump is required.





Rumsey Rotary Power Force Pump. An inexpensive pump of large capacity for elevations up to 80 feet. For handling water, oil, paint, varnish or special liquids.

Sectional View of Heavy Service Rotary Pump, showing the arrangement of the packing strips with which the toes of the cans are provided.

RUMSEY ROTARY PUMPS

RUMSEY Rotary Pumps are the popular choice for all kinds of general pumping. If you want a compact, convenient pump — a pump that costs little and operates economically—get a Rumsey. Rumsey Hand and Rotary Force Pumps will handle almost any liquid that flows—water, oil, paint, varnish, gasoline, grease, tar, ink, extracts, sizes, soaps, chemicals and commercial liquids of all kinds. Liquids corrosive to iron or bronze are excepted.

Would you like to know the results that well-known users are getting with Rumsey Pumps? If so, write us to-day.
